CALIFORNIA
STATE LIBRARY.

*When, from whom, and how this volume was obtained,
with the price paid, if any, may be found opposite
the above number in the Register of Books,
which is always open to inspection.*

Extract from the Political Code.

SECTION 2296. Books may be taken from the Library by the MEMBERS OF THE LEGISLATURE, DURING THE SESSIONS THEREOF, and by other State officers at any time.

SEC. 2298. The Controller, if notified by the Librarian that any officer has failed to return books taken by him within the time prescribed by the Rules, and after demand made, must not draw his warrant for the salary of such officer until the return is made, or three times the value of the books, or of any injuries thereto, has been paid to the Librarian.

SEC. 2299. Every person who injures or fails to return any book taken is liable to the Librarian in three times the value thereof.

No person shall take or detain from the General Library more than two volumes at any one time, or for a longer period than two weeks. BOOKS OF REFERENCE SHALL NOT BE TAKEN FROM THE LIBRARY AT ANY TIME.—[Extract from the Rules.]

42 The Foregoing Regulations will be strictly enforced. 63

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO.,
Publishers.

SAN FRANCISCO, SATURDAY, JANUARY 6, 1883.

VOLUME XLVI
Number 1

Dry Crushing and Roasting Mill.

We illustrate on this page the general plan of a dry crushing and roasting mill as arranged by the Pacific Iron Works of this city. The ore is brought to the upper story and dropped on to the grizzlies which are shown above. The fine ore passes on down, while the coarse ore is broken in the rock-breaker and then passes by chute down to the revolving drier.

What appears to be the furnace on the upper floor of the building is the Pacific revolving drier. This is to dry the ore before it goes into the batteries, and takes the place of the ordinary drying plates heretofore used. The ore is delivered from the crusher (shown in the engraving) directly into the drier, where it is showered through the flame as it is progressed through the cylinder, until discharged at the lower end. It is automatic in its operation, requires little fuel, and needs no attention. The ore is more thoroughly dried than is possible on plates. These driers are made 40"x30" diameter by 16 ft. long and 48"x30" 24 ft. long.

From this drier the ore goes to the batteries, and is then carried up into the furnace, where it is chloridized. The furnace used is the Howell-White, in which are combined the three essential requisites for the thorough and economical roasting and chlorination of ores: 1st. Continuous progression through and discharge of the ore from the furnace while it is being constantly stirred and showered through the heated air and gases, exposing it in the greatest possible degree to their reducing action. 2d. Increasing the heat on the ores as they are progressed through the furnace. 3d. Subjecting the ores to this showering process any length of time that may be necessary, with any given character of ore, for its thorough reduction.

For ores containing base metals this furnace affords a most economical process. The ore being exposed in the very greatest degree, and also for any desired time to the action of the receiving agents of heat, air or gases. The main fire enters the lower end of the cylinder and passes entirely through it. The ore is regularly and continuously fed from a hopper at the upper end, by a screw conveyor into the cylinder and constantly stirred and showered through the heated air and gases, by means of spiral ribs in the small section of the cylinder, and regularly progresses through it and discharges at the lower end into the ore chamber. The length of time is subject to regulation. The auxiliary fire at

the upper end of the cylinder is for the purpose of receiving the finer particles of ore which are carried back by the draft, which constitute, in many cases, 10 or 15 per cent. of the entire product, and which would otherwise be lost.

When the ore comes from the batteries conveyors move it along to the furnace, where the elevator deposits it in the hopper. After passing through the furnace the ore goes to the cooling floor shown below the furnaces. After being cooled it is taken to the pans, and thence passes to the settlers. The retorts are shown on the left. The drier, furnace, retorts and boilers each have independent stacks. A dry crushing 20-stamp mill such as the engraving

A New Amalgamator and Concentrator.

Wm. P. Davis, of 1232 Dupont street, in this city, has just received through the MINING AND SCIENTIFIC PRESS Patent Agency a patent for an improved ore concentrator and amalgamator of that class in which an endless belt travels upward against a stream of water and deposits its concentrations in a tank below.

A tank having an inclined bottom has at its upper end a smaller tank for receiving the concentrations. The main tank is supplied with water from a pipe underneath, and has a discharge in its end near the bottom. In the re-

and against the belt as it travels upward. This pipe is loosely journaled in boxes, to have a certain lateral movement or vibration. The lateral vibration of the pipe causes a distribution of the jets over the belt. Above the belt, lower than the water pipe, is the ore distributor or feed, supplied from a small sluice. Water is also directed upon the belt at the edge of the water line by another water pipe.

In the lower end of the tank is a plate amalgamated on its lower surface and sustained on the surface of the water by means of suitable hangers. This plate extends between the water line upon the belt and the end of the tank.

The belt travels upward by means of power applied at the drum, its largest portion moving through the water. The ore is fed to the belt from the distributor, and moving up, meets the vibrating jets of water from the water pipe. By these jets a separation occurs at this point. The heavier particles or concentrations resist the downward flow of the water, and are carried down into the receiving tank, which contains clear water, and are washed off.

From this they are continually discharged through its bottom. The lighter or waste particles flow down over the belt with the waste water. They contain a portion of precious metal too light to resist the flow. The undulatory motion given by the cam roller, which is a main peculiarity of the machine, tends to settle them down upon the belt, and

GENERAL ARRANGEMENT OF A DRY CRUSHING AND ROASTING MILL.

represents will require an 18x46 Wheelock engine for power.

We learn from the *Pioche Record* that Eugene Blair, formerly of the police force in Virginia, Nev., with two or three prospectors, has gone off on a mining "still hunt" in Southern Arizona. The *Record* says: Although these individuals were very reticent as to what they were going after, we learn they go for the purpose of taking up the mica claims in that locality, of which there are large quantities. The blocks of mica that have from time to time been sent to Pioche from that vicinity are very fine specimens, and as the railroad will be running through that section within a year, these mica claims will probably become valuable, though worthless at present.

GARBER & THORNTON, of San Francisco, have commenced suit in the District Court at Eureka (Nev.) to recover from the Eureka Consolidated Mining Company \$60,000—a balance claimed by them for legal services rendered the company, principally in the great suit with the Richmond Mining Company, determined in the Supreme Court of the United States in March, 1881.

ceiving tank is journaled a driving drum to which power is applied. There are also suitable rollers arranged along the endless belt running over these and the driving drum.

To the belt is given what is known as an "up-hill travel," that is, it travels up the incline over the rollers and around the drum from which it derives its motion. All the rollers over which it passes, including the drum, are individually journaled in boxes provided with sorrows whereby each may be adjusted to vary the inclination or level of the belt at any desirable point, which is an advantage to the ore at different points upon the belt, as has been found by experience. One of the rollers over which the belt travels is cam-shaped, which gives the belt a gentle undulatory motion, which the inventor says is highly beneficial in settling the heavier particles. There is no side shake or end shake to the belt.

The water in both the main and small tanks is kept high enough to submerge the entire belt, with the exception of that portion of its top extending from the top of the main roller to about two-thirds of the way down.

Just over the belt at its highest point, which is above the roller, next to the upper one, is a water pipe arranged to throw jets of water upon

some are thus carried up and washed off in the upper tank. The rest continue down to the water's edge, where they are met by the downward jets of clear water from the supplemental pipe, and more evaporation occurs. What is left descends into the muddy water, and the floating gold is caught under the inverted amalgam plate. Others pass down through the amalgam grate and are caught, while the purely waste matter finds a discharge through the opening.

Thus during the entire operation the pulp is subjected to a concentrator and amalgamatory process. Any kind of belt is used, but the inventor says he has obtained good results upon some kinds of ore with a belt with a friction surface, made by mixing fine sand with the paint applied to a heavy canvas belt.

The legal holidays, other than Sundays, for 1883 will fall as follows: Twenty-second of February (Washington's Birthday), Thursday; 30th of May (Decoration Day), Wednesday; Fourth of July (Independence day), Wednesday; 25th of December (Christmas), Tuesday. Thanksgiving is selected by the President, and usually falls on a Thursday. If Admission day is observed it will be on a Monday, the 9th of September falling on a Sunday.

CORRESPONDENCE.

Notes From Eureka, Nevada.

(From our Correspondent.)

The new Richmond furnace will be started up, it is thought, about the 1st of January. I hear of nothing new at the mines. At the Eureka Con. there is nothing unusual to note. The new (Locan) shaft is at a standstill, and will be so until the sections of the accumulator arrive and are set in place. At the Albion the big smokestacks are finished, and are said by Supt. Robinson to be working with the flue-dust chambers satisfactorily, doing the work required as smoothly as can be desired. Down in the mine developments are progressing steadily day by day, giving testimony to the increasing worth of the property.

New strikes are reported occasionally, but from their position it appears that they are all on the same fissure as the huge Richmond ore bodies, and which extends across the A. C. line in a northwesterly direction through the Albion ground.

The Latest Strike

Made in a triangular cave, dimensions about 33 ft. from north to south, and 32 ft. from east to west. The bottom is filled with debris. On the west wall of it is a body of ore, on which a raise of 20 ft. has been made. Samples taken from different places show the value to be at the rate of \$135 silver and \$6 gold per ton; it also carries 22 1/2% of lead. It is situated on the same level as the October cave, about 120 ft. westward from it.

In the west drift from the east upraise the entire face is all in ore. Twenty ft. below the same is a west drift, just now broken into ore, the distance of the same being 180 ft. from the A. C. line and chamber B, from which large quantities of ore are still being taken.

I understand that the Albion Company have shipped 1,779 bars of base bullion up to Dec. 1st, and from then up to the present time they have shipped 2,899 bars; added to which, the melted bullion in the furnace pit may run the number up to 3,000 bars. Supt. Robinson confidently asserts that when both furnaces are running under full blast he will ship about 10,000 bars per month. If my information from the smelters that No. 2 furnace is not running up to more than two-thirds of its capacity, is correct, Mr. Robinson's statement is made from inference from present results.

Among some of the

Earliest Locations Made in Eureka District Are the mines of the Alexandria Company, but they have been worked by the most primitive methods, and up to the present date with exceeding irregularity. The ores from them were among the first smelted in the district, having been sold at the old Roslin furnace, the only one then in operation here. The Alexandria mine is situated a few hundred ft. above the El Dorado No. 2 main shaft, and is on the same mineral belt of limestone as the Eureka Tunnel ore bodies. From time to time large quantities of ore have been produced that will probably aggregate \$60,000. The expenses of development, reduction works, etc., will reach \$40,000. Several good strikes have been made by parties leasing the property. The company have lately purchased the Sterling series of locations adjoining it, owned by the Sterling Mining Co., a corporation possessed of no other capital than was taken out of the mine. It, however, is undoubtedly a valuable property, that, by the application of adequate means to develop it, will become dividend-paying. A force of men have been set to work grading a road for the purpose of removing the hoisting machinery from the Alexandria incline shaft to a vertical shaft on the Dilligent location, 200 ft. south of it.

This Shaft is Now Down

One hundred feet, and will be carried to a depth of 500 ft., more or less, to the level of the Eureka tunnel, with which it is intended to make connection for the purpose of easy extraction of ore and cheap disposal of waste rock. A wagon road will also be extended from the mine to one now built to New York canyon, which will give thorough and easy access. It is estimated that there are trees on the ground sufficient to provide fuel for running the engine for two years. The ore obtained is generally of good quality, running as high as \$400 per ton. There is also a quantity that is of a grade hitherto unprofitable to work.

At the Lizzie L., in running a drift to connect with a cave discovered a few weeks ago, some ore was struck in a fissure. It is four feet thick, and has been stripped for six feet along the vein; but the extent of the body is not yet known. Assays show a value of \$143 per ton in gold and silver. At the Grant mine nothing but dead work is being done at present. The Geraldine tunnel, now in 130 ft., has to be driven 40 ft. farther to connect with the old workings, out of which very large quantities of rich ore have been taken.

On Adams Hill

The Bowman Company have just shipped 25 tons of ore to the Eureka Con. furnaces that worked over \$100 per ton. This mine is producing favorably.

Grif. J. Griffith, the superintendent of the Walee Con. is in Eureka. He says he will resume work on the mine. Should anything be

done actively the public will be duly informed of it. Last month the Bertrand Company averaged a run of 55 tons of ore per day. It cost \$2.25 to mine, and about \$9 per ton to mill. I learn that the ore yields from 20 to 25 ozs. of silver per ton.

Work has been resumed in the south shaft of the Medora Con. mine, adjoining the old Page and Corwin, and a vein of ore 8 inches thick, very rich, has been struck. Thirty tons of ore are being shipped from the Fairplay mine on the Alhambra hill to the Eureka Con. furnaces.

I hear that the richest ore even taken out of the Bay State mine at Newark, White Pine county, has been struck within the past week. This property is capable of producing large quantities of high grade ore, and still greater of middle class. It is a regular shipper to the Richmond furnaces in Eureka, as are other mines in that locality. Yours truly,

M. H. JOSEPH.

The Transit Observations and Longitudes.

Dr. A. F. Goddard writes to the Sacramento Record-Union as follows: "With regard to the vexed question of longitudes, and the correct time of the several contacts during the transit of Vonne, December 6th, I believe the whole matter can be reconciled something as follows: It appears that we cannot exactly adopt the Signal Service longitudes in another paper. For instance, Professor Davidson's observatory on Clay-street hill and Octavia street, where Captain Gilbert (in charge) took the observation, is in longitude 122° 25' 41s., as determined by Professor Davidson a few years since, whereas the Signal Service still call San Francisco 122° 26' 15s., which was what Lieutenant Trowbridge made Lime Point, in San Francisco bay, in the Coast Survey of 1853-54. It gave the relative time from Greenwich 8h. 9m. 45s., while Prof. Davidson's observatory gives it 8h. 9m. 42.733s., or about 2 1/2s. difference in time. But the Signal Service Washington longitude of 77° 1m. is much more out of the way from the Dome observatory. It is true that it has been variously computed at different times from 77° 0m. 15s. to 77° 3m., which may be found in Black's atlas, published in 1871; but Johnson's cyclopedia, 1877, and Loomis' astronomy, give it 77° 2m. 45s. If we take the relative difference, however, of the late eminent and lamented Dr. Draper's computation of his observatory at Hastings, near New York, which in his transit of Mercury observations, May 6, 1878, he gave as 73° 52m. 25s., or 23h. 47m. 18s. in time, calling Washington 24h. The difference, 12m. 42s., is equal to 31.10m. 30s., which, added to 73° 52m. 25s., makes 77° 2m. 55s. This is doubtless very nearly correct. But special observations for longitude or time from Greenwich, after the electric Atlantic cable was laid, were taken by Dr. Gould, Professor Hilgard and another, which gave a mean of 5h. 8m. 12.12s., convertible to 77° 3m. 1.8s. Washington; so probably that is most correct of all, and is our starting point. Then we deduct 5h. 8m. 12.12s. from Professor Davidson's observatory—8h. 9m. 42.733s.—we have 3h. 1m. 30.613s. as the difference between Washington time and the Clay street observatory; or, if we please, deduct 77° 3m. 1.8s. Washington, from 122° 25m. 41s., Clay street, giving 45° 22m. 39.2s. these should give the same results in time, or show that the Atlantic cable observations were not connected with the same part of Washington. It does give us the same result or 3h. 1m., 3.6 sec., for difference between Washington and the Davidson observatory. Therefore, if we take the given predicted Washington time for the transit and deduct the difference, we shall have the predicted time for Professor Davidson's observatory in San Francisco, Captain Gilbert's place of observation—not of course the Cerro Rohlero N. M., station, where Professor Davidson had such admirable success—except, however, the first contact, which his station seems to have missed, as the sun was less than a diameter above the Organ mountains at the first internal contact. Well, then, the prediction for Captain Gilbert stood:

	Washington.	San Francisco.
First contact.....	3:55 A. M.	5:53 56.4 A. M.
First internal contact.....	9:16 A. M.	9:14 56.4 A. M.
Second internal contact.....	2:33 P. M.	11:36 56.4 A. M.
Last contact.....	3:00 P. M.	11:58 56.4 A. M.

But there is an admirable chart in Proctor's "The Universe and the Coming Transits," showing that ingress is retarded eight minutes at about 105° longitude, and egress accelerated three to four minutes on our coast, and five minutes at about 104° longitude. The second internal or third contact was not due at 11h. 36m., 56.4 sec., but at some figure we must ascertain. It is not quite clear, however, that the eight minutes, or even seven and a half minutes' retardation extends further than the diagonal path shown running from about Wyoming to the Gulf of California, but it undoubtedly indicates important differences which may clear up the observed differences at San Francisco and Sacramento.

Captain Gilbert recorded his observation of the second internal contact at 11h. 42m. A. M. and the last contact at 12h. 2m. 10s., showing 5m. 3.6s. retardation at the third contact, and 3m. 13.6s. at the last contact from the Washington predicted time. But it appears that the well-known medical almanac of Dr. Jayne, Philadelphia, gives the time for thirty-one cities in the United States, including Sacramento and San Francisco, and 11h. 42m. A. M. is given for San Francisco, and we may note that if we deduct three minutes' acceleration from eight minutes' retardation, it leaves the retard-

ation five minutes, or within 3.6s. of the observation, or taking the last contact and deducting 3 1/2m. acceleration from 7m. retardation, it would give us 3 1/2m. retardation, which would be within 3.6s. of the last contact observation at San Francisco. A very little alteration in the proportions of the acceleration and retardation would give the exact results, therefore I have dwelt upon the San Francisco observations because they afford the key to the correctness of Major Bender's at the State Capitol; but now, then, we must ascertain what the longitude of our State Capitol is. Professor Hall kindly informs me that it is 27.85 miles less or east of 122° 1. true longitude. At 351.35m. Sacramento latitude that would give us 121° 29m. 7.4s., while the Coast Survey in 1878 ordered 1m. added to every degree of old longitude, showing that formerly it would have read, after adding the 1m. 121° 30m. 7.4 sec. The Signal Service figure—121° 31m.—appears to be too much. Adopting 121° 29m. 7.4s., then, as the longitude of the State Capitol west of Greenwich, the difference from San Francisco is 56m. 33.6 sec.; for adding that to my computation of the dome of the State Capitol—121° 29m. 7.4 sec.—which has never been given by any civil engineer before, we have 122° 25m. 41 sec. for Prof. Davidson's observatory on Clay street hill. It must be recollected that the Coast Survey Office, Washington square, San Francisco, was called in longitude 122° 24m. 35.49 sec., but no doubt should have been 122° 25m. 35.49 sec. The 56m. 33.6 sec. gives us 3m. 46.24 sec. difference of time, or later than San Francisco, so that, as we found before, that the San Francisco, or Captain Gilbert's observation of 11h. 42m. came out right with the proper retardation added, and conformed to Dr. Jayne's almanac; so if we add 3m. 46.24s., as a result, 11h. 45m. 46.24s., which includes the same retardation as we allowed for San Francisco, and this comes out 13.76s. only less than 11h. 46m. given in Dr. Jayne's almanac. The observation was, in fact, called, as explained last week, at 11h. 42m. 55s., San Francisco time, adding 3h. 46m. 24s.; therefore, we have 11h. 46m. 31.24s., showing that Major Bender was probably 31.24s. late, as he was confident he was, and even admitted 13.76s. more, which would make the actual occurrence precisely what I estimate it should have been, 11h. 45m. 46.24s. My mode of getting the true retardation was only approximate, however. The last contact would work out as follows: Captain Gilbert's was 12h. 2m. 10s., with probable retardation of 3m. 13.6s. included. We have then merely to add the difference of our time, 3m. 46.24s., to 12h. 2m. 10s., making 12h. 5m. 56.24s. The actual time Mr. Shearer called to Major Bender was 12h. 2m. 25s., by San Francisco time; adding, therefore, 3m. 42.24s. The Sacramento time called was 12h. 6m. 11.24s., showing a possibility that it was called 15 seconds too late to be in harmony with Captain Gilbert's. Thus, then, we have arrived at conclusions that harmonize with science and the facts, and prove the correctness of Captain Gilbert's observations. Prof. Proctor's elaborate descriptions and chart for the transit of December 6, 1882, and the really admirable precise figures given by Dr. Jayne's almanac, for which his astronomer is deserving of the public thanks, whereas the *Scientific American*, if it quoted from the Nautical almanac, which I have not yet had an opportunity of seeing, still only gave us the Washington time without the retardation added, and was consequently misleading. It was only a few days since that Dr. Jayne's almanac was brought to my notice, which, together with Proctor's chart, I believe clears up the whole mystery, now that I have ascertained the various longitudes of Washington, San Francisco, and our own State Capitol, which have never been given to the public before. I have labored with zeal and a determination to master the question, and have the satisfaction at least that "truth brings its own reward," and some, at least, of the public, I am sure, will appreciate my endeavor.

New State Officers and Legislature.

The following is a list of the State officers elect, with postoffice addresses of same:

Governor—George Stoneman, San Gabriel, Los Angeles county.
Lieutenant-Governor—John Daggett, Oakland—formerly Klamath Mills, Siskiyou county.
Secretary of State—T. L. Thompson, Santa Rosa, Sonoma county.
Controller—J. P. Dunn, San Francisco.
Treasurer—W. A. January, San Jose.
Attorney-General—E. C. Marshall, San Francisco.
Surveyor-General—W. L. Willey, San Diego.
Superintendent of Public Instruction—W. T. Welcker, San Francisco.
Clerk of Supreme Court—J. W. McCarthy, Modesto, Stanislaus county.
Railroad Commissioners—G. J. Carpenter, Placerville, El Dorado county; W. P. Humphries, San Francisco; W. W. Foote, Oakland.
Board of Equalization—Charles Gilden, San Francisco; L. C. Morehouse, San Leandro, Alameda county; C. S. Wilcox, Yuba City, Sutter county; John Markley, Sinaloa.
Congressmen—Charles A. Sumner, San Francisco; J. R. Glascock, Oakland; W. S. Rosecrans, San Francisco; James H. Budd, Stockton; Barclay Henley, Santa Rosa, Sonoma county; P. B. Tully, Gilroy, Santa Clara county.
Senate.
First District—San Diego and San Bernardino, John Wolfkill, D., Bernardo, San Diego county.
Second District—Los Angeles, R. F. Del Valle, D., Los Angeles.

Third District—Ventura, Santa Barbara and San Luis Obispo, George Steele, R., San Luis Obispo.
Fourth District—Fresno, Tulare, Kern, Mono and Inyo, Patrick Reddy, D., Bodie.
Fifth District—Mariposa, Merced and Stanislaus, J. D. Spencer, D., Modesto.
Sixth District—Monterey, San Benito and Santa Cruz, Benjamin Knight, D., Santa Cruz.
Seventh District—Santa Clara, C. H. Maddox, D., San Jose; B. D. Murphy, D., San Jose.
Eighth District—San Francisco and San Mateo, Jeremiah Lynch, D., San Francisco.
Ninth District—San Francisco, T. McCarthy, D.; John Harrigan, D.
Tenth District—San Francisco, David McClure, R.; George H. Perry, R.
Eleventh District—San Francisco, Edward Keating, D.; T. R. Nelson, D.
Twelfth District—San Francisco, J. T. Dougherty, D.; Martin Kelly, D.
Thirteenth District—San Francisco, J. F. Sullivan, D.; W. Cronan, D.
Fourteenth District—Alameda, Henry Vrooman, R., Oakland; George E. Whitney, R., Oakland.
Fifteenth District—Contra Costa and Marin, W. B. English, D., Concord, Contra Costa county.
Sixteenth District—San Joaquin and Amador, B. F. Langford (joint), D., Acampo; F. T. Baldwin, D., Stockton.
Seventeenth District—Calaveras and Tuolumne, C. D. Reynolds, D., Milton, Calaveras county.
Eighteenth District—Sacramento, Joseph Routier, R., Routier's P. O.; Frederick Cox, D., Sacramento.
Nineteenth District—Solano and Yolo, J. M. Dudley, R., Dixon; K. E. Kelley (joint), D., Fairfield.
Twentieth District—Napa, Lake and Sonoma, Dennis Spencer, D., Napa.
Twenty-first District—Sonoma, George A. Johnson, D., Santa Rosa.
Twenty-second District—Placer, J. A. Filcher, D., Auburn.
Twenty-third District—El Dorado and Alpine, Thomas Fraser, R., Placerville.
Twenty-fourth District—Nevada and Sierra, C. W. Cross, D., Nevada City; H. W. Wallis (joint), R., Forest City, Sierra county.
Twenty-fifth District—Yuba and Sutter, A. L. Chandler, R., Nicolaus.
Twenty-sixth District—Butte, Plumas and Lassen, W. W. Kellogg, D., Quincy, Plumas county.
Twenty-seventh District—Mendocino, Humboldt and Del Norte, P. H. Ryan, D., Eureka.
Twenty-eighth District—Siskiyou, Modoc, Trinity and Shasta, Clay W. Taylor, D., Shasta.
Twenty-ninth District—Colusa and Tehama, C. F. Foster, D., Red Bluff.

Assembly.

Alameda—L. H. Cary, R., Oakland; W. B. Clement, R., Alameda; R. L. H. Brown, R., Haywards.
Amador—A. Caminetti, D., Jackson; Robert Stewart, D., Volcano.
Butte—L. C. Granger, D., Oroville; T. R. Fleming, D., Gridley.
Contra Costa—G. W. T. Carter, R., Byron.
Calaveras—A. K. Wheat, D., Valley Springs.
Colusa and Tehama—Renben Clark, D., Williams, Colusa county.
Del Norte—W. A. Hamilton, D.
El Dorado—C. F. Irwin, D., Placerville.
El Dorado and Alpine—Thomas B. Rowland, D., Rowland's Lake Tahoe.
Fresno—W. D. Grady, D.
Humboldt—H. G. Weaver, R., Eureka.
Inyo and Mono—J. M. Keller, R., Lone Pine, Inyo county.
Los Angeles—A. B. Moffitt, D., San Fernando; H. W. Head, D., Garden Grove.
Lake—H. J. Crumpton, D.
Mariposa and Merced—W. L. Smith, D., Mariposa.
Marin—S. C. Bowers, D., San Rafael.
Mendocino—Archibald Vell, D.
Monterey—Thomas F. Paw, D., Chualar, Monterey county.
Napa—F. E. Johnston, D.
Nevada—J. L. Levison, R., Truckee; A. Walrath, R., Nevada City; J. O. Sweetland, D., Sweetland.
Placer—P. McHale, D., Michigan Bluff.
Plumas and Lassen—Calvin McCluskey, D., Sausalville.
San Francisco—Ninth District—E. Gausrail, D.; W. J. Simon, D.; Thomas F. Barry, D.; James Callaghan, D. Tenth District—Charles A. Muddock, R.; J. H. Culver, R.; B. F. McKinley, R.; A. G. Booth, R. Eleventh District—Peter Wheelan, D.; Thomas Healy, D.; Bernard Rawle, D.; Sydney Hall, D. Twelfth District—T. H. McDonald, D.; M. R. Levison, D.; James J. Flynn, D.; P. Plover, D. Thirteenth District—Charles A. Hughes, D.; D. H. Hibb, D.; Thomas H. Murphy, D.; E. J. O'Connor, D.
Sacramento—H. M. Larue, D., Sacramento; F. D. Ryan, R., Sacramento; Gillis Doty, D., Elk Grove.
San Diego—Edwin Parker, D., San Diego.
San Bernardino—Trueman Reeves, R.

MECHANICAL PROGRESS.

Asphalt Foundations for Machinery.

Parties who find their business interfered with by vibrations produced by a neighbor's machinery are very apt to seek redress at the hands of the law. Such litigation is attended with loss of time and temper, if not of money; it makes enemies of neighbors, and should, if possible, be avoided. The offending party will find it to his advantage to incur considerable expense in abating the nuisance, rather than subject himself to be mulcted in damages to an amount which a jury is to fix. Timber and masonry, the materials usually employed for foundations, have been found to transmit injuriously the vibrations of machinery placed upon them and firmly secured. Similar machinery, similarly secured upon a foundation of asphalt concrete has, when driven at an equal rate, produced no perceptible vibration. The asphalt referred to is a natural product of bituminous limestone, consisting of carbonate of lime and mineral bitumen intimately commingled by natural agency. If to this rock, ground to powder, an additional portion of similar bitumen be added, and the whole thoroughly mixed when hot with clean dry sharp sand, free from all earthy matters, we have the gritted asphalt-mastic so successfully used just prior to the Paris exhibition, 1878, and during that event, for the construction of non-vibrating foundations, by Mr. Wm. H. Delano, engineer of the company organized for this manufacture of that article.

A striking instance of the value of this preparation as a foundation for machinery is given in their own experience. One of the heavy mills used by the company for grinding rock, when running at its usual rate of 500 revolutions per minute, caused a neighboring factory for painting on glass and china to vibrate to such a degree both in the works and in the counting-room that the proprietor threatened to bring suit. The area thrown into vibration by the mill had a radius of over a hundred feet, and the company wisely resolved to remove the foundation of wood and masonry and substitute their own material for it. This was done under both machinery and walls. It is now impossible to know by the vibration when the mill is running. There have never been any yielding, settling or repairs since it was laid.

Subsequently the foundation for a dis press for stamping out iron frames, and striking 12 blows a minute, was laid in asphalt with equal success. Foundations of asphalt for steam hammers at the artillery factory at Vincennes, at the shops of the Paris, Lyons, and Mediterranean railroad, and elsewhere, have also given every satisfaction.

The method employed for the large grist mill making 1,400 revolutions a minute, at the Paris Exhibition of 1878, will serve to illustrate the general course to be pursued in laying such a foundation. An oak frame-work was first built in the excavation, and the places marked for the bearings, recesses, etc., surrounded by a rough caisson of planking, firmly supported by stays from the outside to prevent bulging. A layer of hot gritted asphalt-mastic was then poured on the floor and covered with a layer of flint-stone and rubble, perfectly dry; next a layer of mastic followed by a layer of flint and rubble, and so on, until the top was reached. The whole was then left 10 days to cool and settle. At the end of that time the surface was dressed with mastic and the planking removed. Earth was then filled in all around to the required height, and the machinery fixed and started. At the close of the exhibition it was found impossible to break up this material, and as blasting could not be allowed in the city, this block, weighing 45 tons, remains in the ground of the Champs de Mars, opposite the Military school. The proportions used were 60 per cent. flint and rubble and 40 per cent. gritted mastic. Of the latter about 7 per cent. was bitumen, from which all matters volatilizable at 428° Fah. had been driven off.

We condense the above from the *Textile Record*. In connection with the same we would give the following, which it is said will form a very good floor for a machine shop and even quite a good foundation for the building and machinery to rest upon: First make a proper excavation, then whet in gravel and dirt, ram them down, run water upon them, and allowing it to settle; then adding 6 inches of fine, sharp, olean sand, roll this well with a heavy roller. Upon this lay inch boards, both sides coated with boiling tar. Upon this lay on end blocks of square wood, 5 inches long, one end dipped into tar for two-thirds its length, and set tarred end down.

STEEL VS. IRON RAILS.—The gradual disuse of iron rails is shown by the fact that in the last few months this country has entirely ceased to import them from Great Britain, and that in the eight months ending with August there was a decrease in their exportation from England of 16½%. The steel rail exports, however, in the same length of time, increased from 339,686 to 505,017 tons. Our own rolling-mills are also turning out a much larger proportion of steel rails. The mill at Pueblo, Colorado, are fitted up for making steel rails only, of which they turn out about 1,000 per day.

American vs. English Nailmakers.

Discussing the prospects of the nail trade, a Birmingham (Eng.) correspondent of the *London Ironmonger* says: Foreign competition in this branch is relaxed by the action of American nailmakers, who have advanced prices from 15 cents to 20 cents per keg. These advanced rates, which are much above those demanded by English makers, have of course greatly improved the chances of English nails in Canada, Australia and other neutral markets, though many even in our own colonies appear to be strongly biased still in favor of the American article, owing to the greater uniformity of quality. It is not denied that English manufacturers can produce as good or even a better nail than the Americans, but they do not always do so; and the merchants who conduct the trade are apt in buying to sacrifice higher considerations to cheapness. The Americans are wiser in their generation, and frankly recognize the impossibility of competing with English makers in cheapness; they strive to excel in quality, uniformity and excellence of patterns. On the whole, these tactics have been of great service to them, and have given them a footing in many markets from which it will be no easy matter to dislodge them.

Statistics show that over 85,000 kegs of American nails and spikes were exported last year. They went to over 40 different countries, including England, Ireland and Scotland. Chili took the most, 1,806,500 lbs.; Mexico next, 1,321,512 lbs., and Cuba third, 1,269,120 lbs. The British possessions in Africa took 581,987 lbs. This new departure in this manufacture, of making nails from mild steel instead of iron, will no doubt greatly influence the quality of American nails, and possibly increase the foreign demand for them.

TEMPERING STEEL.—More tools are ruined by overheating, cold-hammering and overtempering than can be redeemed by all the new recipes that have been invented. The only way that is really good is first to find a brand of steel that is good and suitable for the tools to be made, and stick to it. Next find by a few trials the lowest heat that will harden it in pure water at 70° or ordinary shop temperatures. If steel is hardened at the lowest heat, the temper will require drawing very little—i. e., to a pale straw, full straw, or brownish yellow, but not deeper unless for wood-working tools with thin cutting edges, when a full brown may be desirable. File makers use salt water for a hardening bath, because it makes the water more dense, and the teeth harder, and, of course, more brittle. Sulphuric acid or mercury is sometimes used for hardening very small tools for cutting glass and etching stone. For springs the same care should be taken in regard to low, even heating that is necessary with tools. Pure lard oil is as good, and probably better, than any of the many mixtures that have been tried for the hardening fluid. Burning off may do for drawing the temper of small or thick springs, but is totally unfit for long or slender ones. Dip the hardened spring into a bath of oil heated nearly to its boiling temperature. This is the only way to get an even temper.—*Scientific American*.

IMPROVEMENTS IN TEMPERING GLASS.—The high expectations in regard to the Bastic method of toughening glass do not appear to have been fully realized, and any improvement thereupon will be welcomed. That method consisted in immersing the article, while still red hot, in a bath of oil heated to about 390° Fah., and letting it remain there until it had cooled down to that temperature. Glass thus tempered, while tough, seems to be at the same time very brittle, so that when it does break it flies into very small fragments, much like Prince Rupert drops. It appears to have a hard skin, bound tightly over a less hard interior. F. Lühisch, a German, now claims to have devised an improvement on the Bastic process. He immerses the article in a hot bath, heated only to about 220° Fah., but takes it out when it has lost its redness and cools it gradually and very slowly in an oven. He also uses a solution of starch or gum, or some similar substance which does not soil the surface of the glass, as fat or oil does. It is claimed that glass so hardened resists pressure or shocks as well as the Bastic glass, while at the same time it may be cut with a diamond or polished and engraved with the sand blast, a process to which the Bastic glass cannot be safely subjected.

IMPROVEMENT IN WATCH HANDS.—A device in the arrangement of watch hands has been patented, whereby the traveler may see at a glance the time, both at the place he is leaving and whatever local time he may wish to keep at a distance. The value to the traveling public of such a service is apparent in the facility it affords for making connection between trains run at different times, etc. The improvement consists merely in a convenient device whereby a thin hand may be placed upon the dial without any change in the movements of the watch.

POSTS AND GIRDERS.—A writer in *Wood and Iron* says that posts, whether for supporting floors or otherwise, should be bored from end to end to prevent dry rot by allowing a circulation of air. Girders should be constructed with two thicknesses of material with half-inch space between, bolted and keyed together at each end and in the middle.

SCIENTIFIC PROGRESS.

Parasites in a Fly's Tongue.

The microscope is constantly revealing wonder after wonder. The latest observation is from a microscopist at Cincinnati, who has been examining the anatomy of the common house fly, the tongue or proboscis of which he has ascertained is quite commonly inhabited by parasites. The operator had caught a fly, dissected it and taken out the tongue. The reporter of the *Cincinnati Commercial*, who was present, writes as follows:

Under the microscope the proboscis bore a decided resemblance to a rough, uneven log, overgrown with dark, thick moss, at one end of which were a number of black projections having the appearance of heavy spikes driven into the log, but which were in reality infinitely small hairs. It was certainly a formidable looking object in its magnified state. The experienced eye of the professor detected a slight vibration upon the surface of the log, and that particular specimen of fly-tongues was pronounced one of those for which we sought. The tongue was inhabited, and again the fly had proved a success. The operation which followed was one of extreme caution and skillful manipulation, and consisted in splitting the organ lengthwise, which was successfully accomplished under the small microscope, with instruments of most delicate texture, requiring the greatest care in their use. The operation resulted favorably, and sure enough the "critter" was there. He had taken up his residence for the time being inside the tongue, although it has been demonstrated that he possesses the power of roaming at his own sweet will either inside or outside of his field of operation. He was captured without much of a contest, and was imprisoned in a small drop of water, which was placed upon a glass slide with a concave center, and subjected to the searching revelations of the microscope. He appeared to take naturally to his new element, and manifested a surprising activity in his liquid quarters. He was pronounced by the professor to be a very handsome specimen. He was almost transparent, had a flat head and the body of a serpent. And how he did squirm, filling the entire space of his miniature aquarium with his writhings and convulsions. By actual measurement this one was found by Mr. Michelhorst to be 93/1000 of an inch in diameter. The greatest number he has ever found on a single fly's tongue was three—enough, in all conscience!

MIGRATION OF FISH THROUGH THE SUEZ CANAL.—Dr. Keller has communicated to the Swiss Geographical Society some interesting notes relative to the migration of fish by means of the Suez canal. It was at one time predicted that the interchange of fish between the Mediterranean and the Red seas would soon assume large proportions, but the prediction has not been fulfilled. Specimens of the smaller Mediterranean fish have been found in the Red sea, and for some unexplained reason the fish seem to travel in that direction in preference to the other. The most interesting circumstance noted is that the pearl oyster is slowly making its way toward the Mediterranean. Its progress is slow, but it is said to be moving in large companies.

RECENT FINDS IN THE CONNECTICUT VALLEY SANDSTONES.—Some new and very fine specimens of tracks are reported as having recently been found in the sandstones at Turner's Falls, in Massachusetts. Among the find is a bird track with a stride of five feet in length. Compared with a bird which made such a stride the ostrich would dwindle in proportion to a barnyard fowl. This new find in a new locality is considered a very interesting and important one. The entire region of the Connecticut River valley is supposed to have once been covered by the sea, upon the beach of which birds, quadrupeds, insects and various forms of vegetation have left their impressions. Compared with these tracks, as to age, the Pyramids of Egypt are hut as of yesterday.

DISCOVERY OF THE CARBON VOLTAIC ARC.—At a recent meeting of the London Physical Society Professor S. P. Thompson read some "Historical Notes on Physics," in which he showed that the voltaic arc between carbon points was produced by a Mr. Etienne Gaspar Robertson (whose name indicates a Scotch origin) at Paris in 1802. This reference is found in the *Journal de Paris* for that year. Laboratory notebooks at the Royal Institution, however, are said to show that Davy experimented with the arc quite as early. The experiment usually attributed to Franklin, of exhausting air from a vessel of water, "off the boil," and causing it to boil afresh, is found in Boyle's "new experiments touching the spring of the air."

SUN SPOTS.—Herr S. Wolff sends us to account for sun spots by a new theory. He thinks they may represent areas on the sun that are vastly hotter than the vast surface surrounding instead of being cooler, as astronomers generally believe. They are regions so extremely hot, he supposes, that the heat radiations have reached the intensity of ultra violet (red?) rays; these being invisible, the spots consequently appear dark.

Another Great Lake in Africa.

The discovery of another great lake in the interior of Africa is reported far to the west of Albert Nyanza. Occasional reports of such a lake have been current in scientific circles for some time, but it is only recently that any authentic data have been received. Recently F. Lupton, Governor of the Egyptian provinces of Bahr El Ghazal, has written to the *London Times* to the effect that Rafai Aga, an employe under his command, on his return from an expedition toward the Usilo, told him that he and some of the members of the expedition had seen a great lake in the country of the Barhoas, a powerful copper-colored tribe clothed with a peculiar grass cloth (of which Mr. Lupton sends a specimen in his letter). Mr. Lupton gathered that the position of the lake was in about 3 degrees 40 minutes north latitude, and 23 degrees east longitude, and that it was quite as large as Victoria Nyanza. When the weather permits, the Barhoas cross the lake in large open boats made out of a single tree, the voyage taking three days, and they obtain from the people living on the western side (their own country being east of the lake) articles of European manufacture, such as blue heads and brass wire.

Mr. Lupton gives in brief Rafai Aga's account of his trip to the lake, and concludes by saying: "I feel I should not be doing right in keeping dark this information, which, when looked into by competent persons, may throw some light on the famous Congo and Uelle rivers. I believe that the Uelle flows into the lake discovered by Rafai Aga, and that the stream which is said to flow out of the lake probably joins the Congo." Mr. Lupton further informs the *Times* that he is engaged in preparing a map of this province, and that he was about to start in a few days on a journey to a country called Umhungu, some 15 days' march to the west of Dehm Siher.

Electro-Generative Fuel.

At a recent meeting of the French Association for the Advancement of Science, Dr. Brard, of La Rochelle, read a paper before this physical section in which he described a new method of generating electricity by the combustion of a peculiar kind of fire-slab. This slab consists of a brick of carbonaceous matter and a brick of nitrate of soda or nitrate of potash, placed together, but separated by a thin sheet of asbestos paper, and both enveloped in a wrapper of asbestos. The carbon brick is formed of about 100 grams of coal-dust kneaded into a paste with tar or molasses, and shaped in a mold by heat. The mold gives the brick a pitted surface above and perforates it with holes through and through from the upper to the under side. Strips of brass or copper are also imbedded in the under side of the brick to serve as an electrode for the carbon pole of the electro-generative element. The other brick consists of a mixture of three parts ashes and one part nitrate of potash or soda melted together and poured upon the pitted surface of the carbon, which, however, is first covered with a layer of asbestos paper. Strips of brass are also imbedded in this compound to serve as an electrode. The elash thus formed constitutes a generator of electricity when wrapped in asbestos and placed in a furnace or over a fire. In such an element the carbon forms the negative plate and is oxidized just as zinc is oxidized in the ordinary voltaic cell, the nitrate of potash being the oxidizing substance. The slab becomes a thermo-chemical battery, and Mr. Brard states that an electric current is obtained strong enough to actuate an ordinary electric bell. By connecting up several of these elementary slabs after the manner of a voltaic battery, a more powerful current is the result, three or four cells being sufficient to decompose water.

TREMORS OF THE EARTH.—The *London Times* publishes a synopsis of some papers on the "Tremors of the Earth," by the committee appointed to measure the lunar disturbance of gravity and by Mr. G. Darwin, which contains some statements new to the public. It is considered proved by the men of science engaged that the crust of the earth heave under the weights imposed on it till, "when the barometer rises an inch over a land area like that of Australia, the increased load of air sinks the entire continent two or three inches below the normal level." The land actually sinks and rises under the pressure of the mass of water thrown upon it by the tides; the maximum of rise and fall on the Atlantic seaboard reaches five inches. The effect is felt at the bottom of the deepest mine, and may reach for an unknown distance. It follows that the crust of the earth must be of exceeding tenacity, exceeding as a minimum that of granite, and its swaying may be the causes of phenomena hitherto quite unexplained, as, for example, the relation between storm and earthquake. So universal, frequent and unavoidable are these disturbances that the inquiry into the lunar disturbances of gravity has been given up. No depth can be found at which a recording instrument can be placed so as to escape their effect. The round earth pants, in fact, like a breathing being, under changes always going on above her.

PEBBLE-LOADED WATER exerts an astonishing erosive power. In one hydraulic mine a pebble-loaded stream, working eight months in a year, has in four years cut a channel in solid slate rock 3 ft. wide and 50 ft. deep, according to Packard.

MINING SHAREHOLDERS' DIRECTORY.

MINING SUMMARY.

ASSESSMENTS STOCKS ON THE LISTS OF THE BOARDS.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA

ALPINE.

ISABELLE.—*Monitor-Argus*, Dec. 29: In our last issue speaking of the Isabelle G. & S. M. Co., we erred in stating that ore is being taken from a depth of 40 ft. below the top.

mine level, but should have read that the shaft was down 4 ft under that level. The shaft is now sunk 60 ft below that level, and it is the intention to sink another 50 ft before drifting, making 248 ft from the surface. Since our last issue the mill has been started up; also the hoisting works at the Stella mine.

AMADOR.
See — *Amador, Timothy*. Dec. 87; D. Fulkner and th

Gold.—Amador Sentinel, Dec. 21: D. Fulcher and the Bartlett Bros. shipped on Saturday to San Francisco nearly \$1,900 in gold dust, the product of their gravimism at Slabtown. This looks as though Amador county placers were not yet played out.

JACKSON.—Amador Ledger, Dec. 29: Messrs. Peck and Smith arrived in Jackson the middle of last week to make personal investigation and inquiries concerning the condition of this mine. The water was hauled out the same

day, and the parties went down the shaft and viewed the ledge from whence the rich ore, studded with free gold, was extracted the week before. A quantity of the ore was put in a sack and sent below for the inspection of the parties there. It is said that F. M. Brown, former superintendent of the Amador canal, but now of San Francisco, and who has amassed considerable wealth since leaving Amador county by fortunate mining ventures in Colorado, has some thought of embarking in the property. After the spasm of activity, the mine fell back to its previous condition, under attachment, and

change of the mill. The Amador Con. has levied an assessment of 50 cents per share, delinquent January 26th. W. A. Nevills, who, for several months past, has been working on the Spanish Gulch or Mammoth quartz mine near Middle Bar, has taken out some very rich ore, and from all accounts, he is still in quartz of high grade. There is a 10-stamp mill on the property, but it has not been started yet. It is expected to be put in motion shortly, and there is abundance of rock to keep it running. Bartlett's group claim a claim in the spring of 1894. The initial group-up was made lately which proved highly flustering. The auriferous ground will require two or three years to work out.

EL DORADO,

NOTES.—*Mountain Democrat*, Dec. 29: Last Saturday J. E. Lyoo brought down a couple of "goose eggs," the result of a 15-days run at his Mount Hope mine, near Grizzly Flat. The two weighed a fraction over 1½ lbs, and were worth about \$3,150. This was the third clean-up the Mount Hope since the new 10-stamp mill was put up. The mine is paying about \$5,000 per month over all above expenses. Chamberlain's is operation at timber.

above expenses. It is this now in operation at Grizzly and vicinity are regularly turning out upwards of \$10.00 per month. A short time ago 450 lbs of ore from the Albambra mine, Kelsey township, owned by R. H. Ded J. Q. A. Ballard & C. H. Weatherwax, of this city, was sent to Prof. Thomas Price, of Sao Francisco, to be tested. Last week the Professor's return was received, showing a yield of \$2 300, or a fraction over \$5 a pound, \$10,000 p

A RICH COPPER MINE.—W. H. Kesfer, the indefatigable and persistent prospector, came over from Georgetown and has been in Placerville several days, and at Alder drug store he has deposited a considerable lot of fine copper ore taken from a ledge near Garden Valley, which

recently discovered and has partially developed, which he, E. H. Watson, of Georgetown, and others are the owners. He exhibits samples of high-grade sphurated ore, of which he reports a solid ledge 4 ft thickness. Contiguous to this, next to the foot-wall, an 18-inch vein of loose "peacock" ore, which can be freely shoveled up without blasting or picking, and which is even richer than the main ledge. Next to the hang-

wall is a large ledge of quartz, freely interspersed with copper ore, from which also a good prospect in gold is obtained. His location embraces 3,000 ft adjacent to the old Isbell mine, and is in the close vicinity of the ore from St. Lawrence. He has sunk a shaft about 4

A FINE NUGGET—Seth Loveless, on his last trip down from Consumes township, brought with him a bandoleer nugget, weighing a fraction over 2 ozs, recently taken out of his claim, near Brownsville, by Capt. G. S. Clagho, who has taken out many of similar size during the past season.

SOUTHERN INFO.—*Cor. Independent, Dec. 30:* The burning of the Pascamint mill on the evening of the 19th was a serious disaster to this section. The mill had just completed a most successful run of about 6 weeks, the result of which had been estimated at nearly \$50,000, all depending on the prosperity of the camp, when fortune, turning its flood-tide, destroys the mill, and for a time checks the progress of a company who were aiding much toward the prosperity of Inyo. However, as one camp meets with reverse, there are coming forward to sustain the business of the county.

SHERMAN DISTRICT—This district is still moving ahead and the camp, now called Reilly, presents a lively appearance. Some 60 men are employed in and about the mine grading for the mill and erecting buildings. A store, 14 by 54 ft. and 1½ stories high, is being erected. Two

clines are being run on the Bonanza King, and below to mine a working tunnel. The lowest depth reached the main incline is about 130 ft. The company has several men at work upon three other mines—the Natchez, South Point and North Star—with the object of putting them in working order. The history of these mines,

though brief, by no means lacks interest. They were patented, in 1875, by the Wibbsett brothers, who held possession of them and did sufficient work upon the various claims to show that they possessed the merit of having a rich class of ores. At various times they had ore work

that yielded some 250 ozs or more per ton. This, after time, attracted the attention of Mr. John Ely, who placed them, undeveloped as they were, before the Eastern market. In the early part of last spring Mr. Edward R. of New York, made an examination of the mines, and

developed as they were, concluded to take them, some in number. Mr. Reilly visited the mine in October, and immediately ordered the erection of a 10-stamp mill, and upon his return to New York took steps leading to organization of a company. A few months more and

DOINGS AT OTHER CAMPS.—At Snow's canyon Hunt

enough is accumulated the mill will start on a run some 250 tons of gold ore. At Lookout Fitzgerald stands up his furnace on a run of some 250 tons of ore, and mining with an accident was compelled to close down and

der some new water jackets, which will soon arrive, when he will resume smelting. Chloriders and miners at Darwio are actively at work, and the approaching year bids fair for a season of prosperity.

THE MURCHIE MINE.—Nevada Transcript, Dec. 27: 'Murchie mine is looking splendidly, the ore deposit never having made a more encouraging appearance. Next week the work of adding 8 more stamps to those already in operation will be commenced.'

NEW HOISTING WORKS.—Lawrence & Barlow, the contractors, have a good start on the building for the water-power hoisting and pumping machinery at

Sherman Cor. mine. They expect to have everything in readiness within about 30 days, at which time the South Yuba Company contemplate getting water down to them via the Quaker Hill ditch now being constructed.

PLACER.

FOREST HILL.—*Cor. Placer Herald*, Dec. 29: Our mines seem to have caught the infection. For example, the Paragon, which a year ago employed 40 men, now only gives employment to 6. The Napoleon, which 20 earned their daily bread, shut down two months ago, or rather the men quit work, as nearly two months' pay was due them. It may doubtless be started again. The Mayflower and Dardanelles are waiting for their patience and perseverance. That their efforts may be crowned with success is the sincere wish of all in our country. The Baker Divide mine deserves honorable mention.

PLUMAS.

BAY STATE AND STEAMBOAT MINES.—*Greenview Bulletin*, Dec. 23: These claims were formerly known as the Yellow Jacket and White Ledges, and for a long time after first being located nothing was done upon them. During the summer the present owners have put down about 75 ft. of shaft and run 100 ft. of tunnel and drifts. At the surface the ore from both of the ledges prospects very rich. The tunnel now being run was started down the mountain side below the shaft, and will strike the ledge at a depth of 25 ft. from the surface. Every 34 ft. of tunnel gives 2 ft. of backs, the ground being very steep. The same parties own the Monumental claim in the same locality. This they have also been working upon by both a tunnel and shaft. The latter has so far yet to run before it will strike the ledge. The ore in the shaft prospects very well, the gold being distributed evenly through the rock.

GRANITE BASIN.—*Cor. Plumas National*, Dec. 29: At present there is but little hope of gold, but we think within the next 12 months our little camp will have more quartz mines running than have been worked for years. All work has been suspended for the winter, aside from a little prospecting or assessment work, and many have gone out to spend the winter, with the intention of returning in the early spring. There are three families who intend to winter in the Basin and enjoy the "beautiful snow." A few weeks ago the miners of the Basin, pursuant to a call, assembled together and organized a mining district, of 7 miles square, the name of the district being "Granite Basin Mining District." They also adopted a list of district mining laws and elected a Recorder. Hereafter all claims located in the district will be recorded upon the records of this district as they should be. A copy of the mining laws of California mining district was submitted and adopted with but a portion of one section left out. A Davidson was elected Recorder. Although times are dull just at present, we think the outlook for the near future is very favorable, and that our little camp will be one of the successful quartz mining camps of California. The process heretofore used in this locality has not been in any way adapted to the quartz of this district. Parties who came here last August thoroughly examined the quartz, and satisfied themselves that by milling the rock with the proper process for saving the metal, good results, and in paying quantities, could be obtained; also claiming to have a process to work the ore successfully. About the 1st of September Davidson and Lyon bought mining property here, and since that time have been engaged in fixing up machinery preparatory to making a start, towards testing the mines and the process by which they intend to work the rock of this district.

MEADOW VALLEY.—*Cor. Plumas National*, Dec. 30: Everything in this locality is slow. The water has been favorable, but nothing to do since the Monte Cristo mining company was sold out, and times have been down. Edman & Co. are closed up for the winter. Hanson & Andrus are running a tunnel upon the southeast extension, and Bill Smith is prospecting the northwest extension of the Edman ledge. Meadow Valley is as usual, some improvements going on and others in contemplation. R. Jacks is rebuilding his saw-mill. Several residences have been erected on the road-beds between Meadow Valley and Spanish Ranch. Silver Creek mining is closed for the winter. The P. M. & W. Co. are in readiness for water, and have everything complete for a big and long run, should the elements furnish the necessary power. The Orr company has been running, so I am informed. Reports from the river are that times are dull—all, with few exceptions, laid up for winter. How different it might be if some of our selfish moneyed men would only organize a company on purely business principles and build a narrow gauge railroad up said river from Oroville to Quinn. Instead of saying, "Laid up for winter," business would flourish the year round, and all the bars, hotels, etc., on the entire route would be decked with cottage homes and orchards, and instead of less than 100 inhabitants, one or more thousands would be there, and then the untold thousands that remain in the deep and back channels could have machinery placed upon them to advantage, and fortunes could again be made. Besides, it is the only true and feasible route over the Sierras.

SHASTA.

IAO.—*Shasta Courier*, Dec. 30: E. L. Ballou, as well as Crum & Hubbard, are running arrastras and making for themselves a rainy day for many days. Their mines have paid well, and they are satisfied with the outlook. At the Bullion mine, owned by Robinson Bros., everything was working well, and, as a result of good financial returns, the boys were all happy. Honniken & Co., at the Continental, are doing good work and receiving good returns, having plenty of good paying ore on hand. While at Cooper's mine the filthy lure was being extracted from the earth in quantities that remunerate its owner sufficiently for the labor and effort expended, these mines are not what are termed bonanza mines, but are like many others in the county, paying very good wages for effort put forth, and giving to their owners by gradual accumulation efficient returns to enable them to live at ease in after years.

SIERRA.

FOREST CITY.—*Sierra county Tribune*, Dec. 23: The Bald Mountain company is working the usual number of men. Gravel that prospects \$2.30 to the car was struck last week in a tunnel running west from Lowell avenue. This development will result in the company opening out a large piece of ground in a quartz where such prospect was not expected. The Ruby mine continues to pay well, and is being opened out so that a large crew of men can be put at work next spring. The Extension company are prosecuting work in their usual energetic manner, and are very confident in reaching pay again soon. The Arizona company, composed principally of Forest City gentlemen, feel jubilant over the late decision rendered in their favor by the Supreme Court. The Ruby mine, where it is, the company propose to begin work early in the spring.

CHIFFS FLAT.—The Rainbow mine is in full blast and is doing well. Some \$90,000 has been expended by the company this summer in making outside improvements and in developing the mine. The hoisting works are no longer used, but the entire work of the mine is now carried through the new tunnel. At the entrance of the tunnel there have been erected a blacksmith shop and a dump house. Ore is transported from here to the mill by a Halliday tramway. The company intends sinking on the ledge from the new tunnel soon. A Corliss engine and steam pump that is to be used for that purpose is already at the mine. The Rainbow has yielded about \$270,000 of bullion during the past year, which is not a bad showing by any means for a low level. The writer is under no obligations to Supt. L. Irwin for favors.

ALLEGANY.—But few changes have occurred at Allegany during the past summer. Our friends are still there awaiting the development of a "mining boom," which they anticipate will come ere another year rolls around. The Golden Gate mine is still lying idle, with but little prospect of being worked up very soon. It was expected that work would be resumed on the Harlem mine

during the summer, but for some reason it was not. Frank Hauber has really found a bonanza in a quartz ledge. For several months he has been prospecting the ledge, and from nearly the first found the most favorable results. A sack of ore recently shipped to San Francisco assayed \$270 per ton. Mr. Hauber has considerable more of the same kind of rock on the dump. T. H. Sni has also prospecting a ledge that promises to develop into something worth owning. The Buckeye gravel mine, owned by Messrs. Hackett, Patton & Barnhart, has paid well this year. From Will A. Hanly, who has the Golden Star drift mine leased, we learn that a body of blue gravel was recently encountered in that claim that promises to develop very favorable.

MINNESOTA.—*Mountain Messenger*, Dec. 30: Considerable mining still continues in this old time camp. San Ireland is vigorously pushing his bedrock tunnel ahead to prospect his quartz ledge, courting east and west, as well as Rainbow, now in 900 ft. An air tunnel is being put in a distance of 175 ft. that will require about four months' time. This will be then extended 150 ft. further to tap a second ledge, parallel with the first. Two years ago Mr. Ireland panned out with a band mortar \$8,000 from his rich quartz. Near by, in early days, \$5,000 was taken out of one shaft, and from another over \$8,000. San is hopeful of discounting this, as he is patiently awaiting the results of his work. The Yearling mine, San Ireland's rich finds. The Wisconsin gravel company, M. Post, Esq., superintendent, employ 5 men, doing very well this winter, with flattering prospects for the future. W. W. Cooper is now 800 ft. in soft bedrock with his tunnel, and may strike through into gravel any minute. A bedrock tunnel is being run into the Swanee gravel claim. Plumbago and Hope quartz ledges are not being worked at present. Attention is being given to the Fellows' quartz ledge, owned by Eastern capitalists.

NEVADA.

WASHOE DISTRICT.

MEXICAN.—*Entreprise*, Dec. 30: Good headway is being made in the joint Union Consolidated east crosscut. It will be advanced some 20 ft. this week. As yet no special change of material has been noted. The joint Ophir winze is now within a few feet of the 3,000 level. It will reach said level next week. Yesterday quartz was again coming in at the bottom, showing that the lump of porphyry encountered two or three days ago was a boulder.

HALE AND NORCROSS.—The joint Savage drift on the 2000 level is in a distance of 30 ft. The face is in a mixture of quartz and porphyry, which carries a small amount of metal. The ground is soft, and requires to be closely timbered. Since striking the quartz there has been a slight increase in the water. The drift has been cut, the drain boxes are all in, and the water does not interfere with the operations of the workmen.

SAVAGE.—The joint Hale and Norcross drift on the 2000 level is now out some 30 ft. in Hale and Norcross ground. Day by day yesterday a considerable amount of quartz of good appearance, and carrying some metal, made its appearance in the face. This ground is soft, and requires to be closely timbered. When the quartz came it brought in a small increase of water. The drift will be pushed ahead to the Savage line as rapidly as possible.

SIERRA NEVADA.—A new east crosscut joint with Union Consolidated has been started on the 2000 level. The east crosscut on the 2700 level is out some 30 ft. From this point it will probably be necessary to keep a hole drilled ahead, in order to guard against water. The winze from the 2300 down to the 2100 level is being overhauled and repaired.

CALIFORNIA.—Work at the face of the joint Consolidated Virginia southeast drift has been discontinued, in order to cut a drain and properly timber up. Some very promising streaks of quartz, that carry metal, have made their appearance in the face of the drift. The work of overhauling the machinery and apparatus at the C. and C. shaft is about completed.

CONSOLIDATED VIRGINIA.—The southeast drift on the 2700 level, joint with California, is being timbered up, and a drain being cut in the bottom. Streaks of quartz that yield assays have made their appearance in the face of the drift. The surface machinery at the C. and C. shaft is being overhauled, and will be in good repair by the first of next week.

OPHIR.—The main south drift on the 2000 level has crossed the north line of the California ground. The joint Ophir winze will reach the 3,000 level next week. After having passed through a boulder of porphyry, the bottom is again in material largely composed of quartz.

BEST AND BROUGHTON.—Work has not yet been resumed in the north drift. The ground ahead seems to be quite wet, and it is still being allowed to drain out through the drill hole. The flow from the hole is gradually diminishing, and there is not now much pressure.

YELLOW JACKET.—The amount of ore extracted from the old level at the Winters shaft is being steadily increased.

BRISTOL DISTRICT.

STRIKE.—*Picacho Record*, Dec. 27: There has been quite a little strike of ore made in the No. 2 mine of Bristol Co., owned by R. C. Barton & Co. The report is that the ore goes \$50 per cent. lead and from \$100 to \$300 in silver. A new shaft was being sunk on the claim, where there were indications of ore, and at the depth of 6 ft. this new find was encountered. We hope that the report is correct.

WILM START UP.—The Bristol S. M. Co. is preparing to start up its mill on tailings. Mr. Goodhue was in town during the week, employing hands. The Bristol Co., at no distant day, will again be working under full force.

CENTRAL DISTRICT.

PINE ORE.—*Silver State*, Dec. 26: Alex. Wise returned from a visit to his mine at Central yesterday. He says they have at last a new formation in the Keystone shaft, and the ledge carries 3 ft. of sulphure ore, but he cannot tell how rich it is, as none of it has been assayed yet.

CHERRY CREEK DISTRICT.

THE STAR MINE.—*Eureka Sentinel*, Dec. 30: Cherry Creek is still a bustling little camp, in which everybody seemed to be employed, and to have some money for the necessities, as well as the luxuries, of life. The main shaft, which is being run by the 10 stamps, is now in dry running, and running at full capacity, but not at a profit just now, as the most of the ore being reduced is of low grade and does not pay. Of this character of ore, from \$0 per ton down, there is a vast quantity in the mine. At present Mr. Foulke, the superintendent of the property, who is a very intelligent gentleman is experimenting with 1 stamp, wet crushing and concentrating. He has not completed the experiment, but he has had good success. It is to be satisfied that by the use of a series of blanket sluices and a pair of reservoirs, in which to save the sediments, that he can save 10 per cent. of the assay value of the ore, which has hitherto been lost. If he succeeds in this, as he confidently believes he will, it will assure the Star mine a splendid future and Cherry Creek a long life. The process employed in the mills hitherto, and which the 10 stamps are now run, is dry crushing and rearing. Cherry Creek enjoys peculiar advantages, and if Mr. Foulke works out the problem of reducing his low-grade ore profitably it will be a fine town for business. It is what Stephen Gage calls a "competitive point." Being so near Utah, it can get its supplies from Salt Lake if the C. P. refuses low rates of freight. These rates it gets on freight hauled from Toano. Wood is very cheap. Machinery is abundant at \$0 per cord, and a splendid quality of nut pine at \$5.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, Dec. 23: A distance of 10 ft. has been advanced in the new shaft from the 5th shaft level during the week. It is now down 4 ft., and shows a much harder formation than at the time of the last report. The streak of sulphurets encountered has passed entirely out of the winze. There is quite an improvement on the fourth shaft level, the ore body having advanced considerably as well as improving in grade. The main drift on the first shaft level has been extended 15 ft., and the slope above this level is now looking finely,

showing no diminution either in the quantity or quality of the ore produced. The other shaft levels present about the same appearance as last week. In the levels above the 4th there is no important change. The ninth and tenth levels are looking well, and continue the usual yield of ore. All work in and about the mine is progressing favorably. The daily output of ore has been about 65 tons. Work has been resumed in mill No. 2, which was started up on Monday, the necessary repairs having been made meanwhile. Mill No. 1 is closed down, and a complete clean-up will be made in it as soon as possible. The haulage shipments amounted to \$18,654.31 for the week ending December 25th, and a total of \$61,237.45 has been made so far this month.

COLUMBUS CON.—The usual amount of work has been accomplished on this property during the week. The west drift on the first level is now in a distance of 90 ft. At this point an improvement has been started on the ore body. The east drift, on the second level, has reached a length of 62 ft., and is showing a ledge of high-grade ore 18 inches in width. There is no change worthy of note in the west drift, which is now 23 ft. in length.

COMO DISTRICT.

EUREKA.—*Lyon Co. Times*, Dec. 29: Antonio Petacna, the locator and proprietor of the Paymaster, returned to Como about a month ago, and has since been in conference with the mine, Mr. Petacna reports that San Francisco capitalists are keeping posted in regard to Como and the developments in the Eureka, and that if this mine fulfills its present promises there will immediately be a rush of capital to the camp.

EUREKA DISTRICT.

ALEXANDRIA.—*Sentinel*, Dec. 29: The Alexandria Co., hitherto operating the Alexandria mine on Prospect Mountain, has purchased a number of claims lying south of and adjoining their property, known as the Sterling series. The latter has been operated for several years by Adam Hall, who, unaided, except by means realized from the sales of ore taken from his mine, has done an immense amount of work on the ground in running tunnels, sinking shafts, driving drifts, crosscuts, etc. All very trustworthy. Mr. Hall has stuck to his claim through a period of many years, relying on a good credit to carry on the work of exploration when money gave out, and has at last met the reward his energy justly deserves. The work of development upon the consolidated mines of the Alexandria Co. will now be pushed ahead as fast as possible, with a plenty of money to back it. The hoisting engine lately placed upon the Alexandria mine is being removed to the Diligent shaft, now down to a depth of 100 ft., and which will be carried down to a depth even with the level of the Eureka Tunnel, with which connection is to be made by a drift about 500 ft. in length. This will give to three mines, the Alexandria, El Dorado Con. and the Eureka Tunnel, a perfect system of ventilation, cheapening and facilitating the work of development in all of them. The Alexandria mine has yielded large amounts of high and low-grade ore, and the Sterling has been a bonanza mine. The latter the present owners are wealthy merchants of Detroit, Mich., who, from the intimate knowledge we have of the mines, we feel assured will not have reason to regret the investment they have made.

JACKRABBIT DISTRICT.

WORK.—*Picacho Record*, Dec. 27: Considerable work is being done on the Jackrabbit district. John C. Lynch has a force of 5 men working on the Cottontail mine, which is looking very favorable.

SILVERADO DISTRICT.

ONE SUMMIT.—*Eureka Sentinel*, Dec. 30: Foley and Kilgore shipped yesterday to the Kurks Con. reduction works from the Fairplay mine, Alameda Hill, Silverado district, 14 tons of ore—4 tons of first-class and 10 tons of second class. The first assayed \$200 per ton and the second \$80. The mine looks very well.

SWEETWATER DISTRICT.

QUINN.—*Cor. Esmeralda Herald*, Dec. 30: The Summers mine starts up to-day with a full force, and Messrs. Bennett & Reddy, as co-owners, representing one-fifth of the mill and mine. The property never looked as well as it does at present. Four hundred tons of very fine ore await reduction at the mill, which is having its amalgamating capacity enlarged by the addition of two pans and a settler, which were formerly belonged to the old Moses mill at Pine Grove. Everything in mining circles here has been very quiet during the last few days, owing to the many attachments levied on the Summers property; but the gloom that has prevailed has been dispelled, which makes the heart of the average prospector buoyant with hope. It looked at one time as though we were to have a lawsuit of no small proportions to determine the title to the Summers mine. The laws of the country, though founded on reason and sanctified by the wisdom of centuries, afford but a feeble and inadequate protection from the claims of those who shirk the burden and labor of prospecting, and emerge from obscurity to claim the fruit produced by the industry and perseverance of others.

TUSCARORA DISTRICT.

ELRO COS.—*Times Review*, Dec. 28: Main drift of shaft No. 1 has been advanced a distance of 3 ft. The formation still continues hard, but favorable.

NORTH BELLE ISLE.—Total depth of the shaft to date, 290 ft. Suspended work on the 25th inst. to replace some tubes in the hoiler and make some repairs to the machinery.

INDEPENDENCE.—Total depth of No. 1 shaft, 193 ft; progress during the past week, 5 ft. No change in the vein or grade of ore. West crosscut, 200 level, extended 15 ft. Stamps are yielding some good ore.

NAVAYO.—Crosscut, 450 level, extended 12 ft. Formation looks encouraging. No change to note in the stopes. They are producing a good grade of ore at all points. Have resumed work in the south drift on the east lateral vein, 350 level. The vein is yielding some very rich ore.

GRAND PRIZ AND ARGENT.—East drift, 700 level, is in 240 ft., and west drift 350 level, 210 ft. The latter is yielding very fine material. Argentine vein 63 ft. deep. Have changed the grades under all the boilers, and are now using coal, which gives very satisfactory results. Will now get in the plunger pump in the bottom of the shaft, and take out the steam pumps, which will save a great deal of fuel.

WASHINGTON DISTRICT.

A GOOD MINE.—*Esmeralda Herald*, Dec. 28: Oliver Peartree, of Washington district, East Walker river, was in town Monday. He has 5 men employed extracting ore from his mines, some of which he concentrates himself and the balance he ships to Dayton to be worked.

WILLOW CREEK DISTRICT.

ORE.—*Silver State*, Dec. 26: Last week the Silver State reported that a body of fine ore had been found in the Iowa mine at Willow Creek. Joseph McColey, one of the principal owners of the Ohio mine, in the same locality, arrived in town Saturday, and confirmed the report. He says two men break down from 4 to 6 tons of \$100 ore in the mine on a shift. The extent of the ore body is not known, but the appearance of the lead indicates that there is a large body of ore. The Ohio mine is also looking well, and now that there is a mill in the district, it is expected that there will be regular shipments of bullion during the winter, unless the weather is too severe to get ore from the mines, as roads have yet to be built and fuel procured.

GOOD MINING PROSPECTS.—*Silver State*, Dec. 27: E. E. Burr, who arrived here yesterday from Willow Creek on his way to New York, reports that the Willow Creek mines are prospecting better than the most sanguine expected. In addition to the fine body of ore found in the Iowa mine, good ore has been struck in the Missouri and Red Rose mines, and the prospects are very encouraging. In the Shrewsbury mine also the ledge looks well and carries considerable ore. The Silver Wave mill will be started this week to test the machinery, and will commence crushing ore immediately after New Year's day.

ARIZONA.

FOUND ORE.—*Arizona Citizen*, Dec. 29: The Commonwealth M. Co., of Los Caecias, after having expended some \$1,500 in prospecting their mine in Wood Canyon, have found on the 120 level a vein of ore, the average assays of which are \$200 per ton, gold and silver. The average width of the ledge is 6 ft. Many had given up on the Commonwealth Co. had worked so long—almost one year—without finding anything. But now all have greater faith in the future of the camp, and know that the intelligent and persevering work will bring the camp from a dying condition to the lead of the go-ahead camps of the Territory.

CLIP MILL.—*Arizona Sentinel*, Dec. 23: On the first steamer that leaves here the machinery and supplies for the Clip mill will go up. The mill will be erected at Clip Landing, which is about two miles above Red Rock Gate. The mill will be of 10 stamps, 4 pans and 2 settlers. There is power enough to work 10 additional stamps when required. Mr. H. Shipman, one of the owners of the Clip mine and mill, will personally superintend the erection and running of the mill, and expects in six weeks to begin crushing ore. Men are at work grading the road between the mine and the millsite, a distance of about six miles. Reports from the Clip mine are very encouraging. That old-time Arizonian, Mr. A. G. Hubbard, is in charge of the mine, which is a sufficient assurance that the property is well managed.

COLORADO.

UNKNOWN.—*Georgetown Courier*, Dec. 19: From 5 to 11 inches of pyrite, gray copper, and galena has been encountered in this ledge, on Griffith mountain, which mills \$100 per ton.

DIVES.—It is said that Von Brandis & Co., lessees on the East Dives, have a fine vein of ore in the bottom level, which runs well enough to make them feel happy.

CUCKOO.—A lot of coarse galena, carrying rich minerals in the disintegrated portions, was struck in the Cuckoo lode, Republican mountain, last Saturday. It contains 65 per cent. lead, and will mill about 100 ounces silver per ton.

ERNEST STAN.—A very acceptable Christmas present in the way of a big strike in his Vice President mine on Sherman. He has about 3 to 4 inches solid mineral, consisting of galena and gray copper, which runs something like 500 ounces of silver per ton.

CONCORD CRY.—The Diamond Tunnel has cut a 5-ft. vein of mineral at its intersection with the Corry City lode, which assays from 42 to 821 ounces silver per ton. Work will be commenced on the vein as soon as the tunnel head is far enough advanced to admit room.

KOHINOOR AND DONALDSON CONCENTRATOR.—On Wednesday morning of last week, a short distance below the mouth of Fall river, ground was broken for the foundation mill in the Rocky mountain area. The new works are to be erected by the Kohinoor and Donaldson M. Co., the latter corporation which lately has acquired extensive mining properties in Gilpin and Clear Creek counties. The mill will have a capacity for treating 200 tons of ore per day, which will be furnished by the Donaldson and Champion mines, the former being on the south side of the creek and the latter on the north side, each of which will be connected with the mill by wire tramways. The machinery will consist of Hartz jigs and fine vanners, with which the ore has been tested with excellent satisfaction. A contract has been made with Fraser & Chalmers, of Chicago, for the entire plant of machinery, and the works will be pushed forward to completion with all possible dispatch.

IDAHO.

BULLION.—*Silver City Avalanche*, Dec. 23: The largest shipment of treasure at any one time for many years passed through this place last Sunday, in charge of Wm. Paxton, Wells, Fargo & Co.'s messenger, on its way to Winnemucca. We are informed that the value of the shipment was nearly \$30,000.

Most of the ledges in this vicinity are looking well, and considerable ore is being extracted, yet there is not a mill running in camp. Most of the owners of mines have relied upon the winter fresh snow enough, to make good sleighing. So far they have been disappointed, as there is neither wheeling or sleighing, and as a consequence the mills are all shut down for want of ore.

ORO FINO.—*Nex Perce News*, Dec. 21: Mr. Keane, who came down from Oro Fino last week, informs us that the times in that camp have had the poorest season for years, owing to the limited water supply, but they are sanguine of doing well as ever next year. Several locations have been made by new comers on the agricultural lands adjoining the Wee-wee, and the new settlement on Whiskey creek is still flourishing. There is a bright future in store for old Shoshone when the Nex Perce reformation is opened, and time will prove that we are right in asserting that north Idaho is the foothills of the promised land.

MONTANA.

BUTTE.—*Miner*, Dec. 29: At the mines advantage has generally been taken of the holiday season for a general clearing up and reorganization of the works, and the effect of a general relaxation from vigorous production of work is evident in the decreased volume of bullion shipments.

MOULTON.—A full force had been worked up to last night, but the ore house being full to its utmost capacity, the mine will be shut down until after Christmas. During the week a winze has been started from the 200, at a point 200 ft. east of the mine shaft, and the work under the body of ore is being done in sinking that shaft. A 2-ft. vein has been uncovered in the new winze, which mills 50 to 60 ounces.

THE ORIGINAL has been getting ready for active sinking work. The mine has heretofore been worked only to the 200 level, but the shaft had reached a depth of 240 ft. The 40-ft. sump had become filled up, and the work during the past week has been confined to clearing it out.

ALACE.—Development work has been prosecuted on the 700, and stopping as usual on the upper levels.

A LAROE force is working the Magna Charta, and 40 tons of ore per day are hoisted. The high-grade ore mentioned last week as being uncovered in the north drift of the 200 and 300 holds out as to quantity and grade.

M. C. & V.—Working during the week has been principally confined to sinking and development. The strike in the 118 level holds out strong, and it is believed will prove one of the most valuable discoveries in the mine.

NEW MEXICO.

BLACK RANGE.—*Cor. New Southwest*, Dec. 29: Having just returned from a prospect over the country on the east side of Black Range, a few items regarding this now bonanza Territory might prove interesting. Chlorite is fast developing into a fine camp. It is growing rapidly. Its mines are being opened to their advantage, and the mining is going on. Among the best mines are the White Sulphur, Wall Street and Colonial. Nearly every canyon (from one to two miles apart) running east from the summit of the Range has its good mines. The Princess, on the Cave creek, has a fine showing of sulphide ore. It has 2 ft. of the vein matter claimed to average 100 ozs. Thomas C. Archer, one of the best posted prospectors in the country, has some very fine prospects in this Territory. He is going to the next gulch south are the rich mines of Charles Van Alstyne. His best mine is the "Ingersol." This claim shows from 15 to 24 inches of partially decomposed quartz, lying between perfect walls. Character of ore is sulphides. The formation is porphyritic-granite. On the middle Percha we find the famous Solitaire and St. Clair mines. The Solitaire vein has at last been found. It is wonderfully rich. Many other fine prospects are lying undeveloped on this level.

The Denver Exposition—No. 19.

[Editorial Correspondence.]

The Nevada Exhibit.

The ores and minerals on exhibition at Denver from the State of Nevada, although few in number, small in bulk, and packed away almost out of sight in one corner of the building, nevertheless, to the mineralogist comprised one of the most interesting collections in the entire Exposition. The collection embraced nearly all the valuable minerals and metals known to science. In no other exhibit could a person gaze upon ores that have been extracted from a depth of over half a mile beneath the earth's surface. In that exhibit were to be seen free milling ores from the Comstock; smelting ores of varied character from Eureka and Esmeralda counties and from surrounding districts; roasting ores from Austin, Ophir, Cornucopia, Tuscarora, Lewis, Humboldt and Esmeralda counties; copper ores from Lander, Washoe, Nye and Esmeralda counties; horn silver from Tuscarora, White Pine and Esmeralda; gold from Paradise, Tuscarora, Virginia City, Lewis, Eureka and White Pine districts; stephanite, ruby silver and chloride ores from Austin; stettinite from Nye county; garnets from White Pine; native copper from Lander and Esmeralda counties; mineral soap from Elko; salt, borax and soda from Esmeralda county; niter and sulphur from Humboldt county; nickel and cobalt from Nye county, and iron ores from various portions of the State.

No other State or Territory represented at that exposition exhibited refined or crude borax. Nevada presented a fine display of refined borax, borate of soda, borate of lime. Cotton balls and tinkle in large hermetically sealed glass jars were exhibited from the famous Teels Marsh deposit, of Esmeralda county, owned by Smith Bros., as also like samples from the Pacific works, owned by F. M. Smith. The salines attracted no little attention, and called forth many questions from those unfamiliar with the nature, process of refining and the many industrial uses to which they were adapted. The production of borax is one of the principal industries of the State.

At the closing of the Exposition the Nevada Commissioners turned over the exhibit of that State to the manager of the Union Pacific Railroad exhibit, at Denver, to be kept there as a permanent exhibit, and Commissioner Smith, moreover, agreed to collect additional minerals from the State of Nevada and send to Denver to be added to the Nevada collection already there, thus giving the State of Nevada a permanent exhibit with the Union Pacific railroad at any future exposition.

The collection, as shown by the Commissioners, E. T. George and B. G. Smith, though embracing ores from all parts of the State, was far from being what it might have been had sufficient time been given for a thorough canvass of the State. Many of the most important and promising mines were not represented at all. The entire collection was but the work of a few days, and altogether a private enterprise. The Legislature meeting but once in two years, and the Exposition at Denver not being known at time of its previous meeting, no appropriation was made to meet expenses. But in order that the State might not be entirely without any representation, Messrs. F. W. Dunn, Superintendent of the Nevada Central railroad; A. A. Curtis, banker, and I. A. Blossom, contractor, miner and stock raiser, all of Lander county, and F. M. and B. G. Smith, of Esmeralda county, nobly came to the front and paid the expenses necessary to insure Nevada a representation at the great National Mineral and Industrial Exposition at Denver. Such public spirited citizens are a credit to the State, and the Legislature of Nevada should see to it that the amount is reimbursed to those gentlemen, and a vote of thanks extended for their prompt and noble action in the matter.

There is no need of our describing the amount of work which has been performed on most of the leading mines of Nevada. Our readers are already familiar with that work in all its magnificent proportions. Suffice it at this time to say that several Nevada mines have reached a depth of nearly 3,000 ft., and that the Comstock lode alone has added more than \$350,000,000 to the circulating medium of the world, and that the many promising camps within her borders are still adding to the world's wealth their quota of gold and silver, and many of the useful metals. In the southern portion of the State new discoveries are being opened up and a large industry being built up, not only in mining for the precious metals, but in adding to the world's commerce large quantities of salt, borax, and soda; and notwithstanding the present business depression, we venture to predict that ere long Nevada will once more take her place in the front rank as a bullion producer, and that her mines of other metals and minerals will become the wonder and admiration of the civilized world.

It is to be hoped that the Legislatures of Nevada and other States and Territories will make the necessary appropriation for having a suitable person appointed to visit the different mining districts and obtain collections of ore from all the prominent mines, so that next year a full representation of the mineral wealth of the Pacific States and Territories may be placed on exhibition before Eastern and European capital-

ists. An announcement has already been made that another grand Exposition will be held at Denver next summer under substantially the same management that so successfully planned and carried out that of last summer.

W. B. EWER.

PRODUCTION OF VANADIUM FROM FURNACE SLAG.—It is well known that the cinder of the Thomas Gilchrist process contains very valuable elements, extensive experiments having, for instance, been made to pulverize it and use it as manure. We learn from a paper presented to the French Academy of Sciences by MM. G. Witz and F. Osmand that the authors have succeeded in producing vanadium from Thomas slag. Vanadium, discovered in 1830 by Sefstrom, occurs, besides in a few rare minerals, in many iron ores and other rocks, but in such small quantities that its separation is attended by great difficulties. Vanadium was first used by Lightfoot in 1871 in wood dyeing for changing aniline into aniline black. It possesses the additional property of increasing the luster of the color and the sharpness of the impression in printing on cotton. It is also used for photographic purposes, in painting china, in the manufacture of ink, and in tanning wine. The price of vanadium is at present very high, owing to the difficulty attending its extraction. Vanadate of soda costs from 25¢. to 30¢. per pound. To show the importance of the above discovery to works carrying on the dephosphorizing process, it may be mentioned that in the Crenset steel works alone 60 tons of vanadium might be annually produced.—*Iron.*

IMPROVEMENTS AT THE TANITE CO.'S WORKS.—It is only a few months ago that we chronicled the enlargement of the Tanite works by the addition of several large buildings, which are moreover among the most substantial structures of the kind in the county. But "Tanite" is a synonym for busy activity and energetic progress. It would be unusual for a monthly visitor to fail noting on each return some improvement. The new store house, 24x40, two stories and attic, which became a necessity with the rapidly increasing amount of work turned out, is now thoroughly finished. The company have also just built a new casting shed, 16x30, one story high. They have also just completed the extension of the boiler shed, adding 19 feet to the original one, which is now 50 feet long. They have just put in place a new horizontal boiler, built by Tippet & Wood, of Phillipsburgh, N. J. It is one of 65 horse-power, 15 feet long and five feet in diameter. It has 45 tubes which are four inches in diameter. This boiler is in addition, of course, to one of the same size in present use. They have also just added to their machinery a new Worthington double-acting steam pump, to be used as an auxiliary to the "Nigara" (Campbell & Hardick) pump now in use, both for boiler feeding and for use in case of fire.—*Jeffersonian.*

CALICO DISTRICT.—This comparatively new mining district, in San Bernardino county, is thus hopefully spoken of by the *Colton Semi-Tropic*: Calico has passed through its most discouraging experiences, and is now fairly started on the road to prosperity. The activity in mining operations is constantly increasing. Assessment work is being done on a great many claims; valuable claims are being sold to parties who have the money to develop them; extensive and substantial improvements are being made on the principal mines; good roads are being built which are accessible to all of the best mines; the Oriental mill is rapidly approaching completion; the railroad is completed, depot buildings six miles from town have been erected, and we now have rapid communication with the rest of the world; in town buildings have been enlarged, and preparations are now being made to erect other buildings; stores are increasing their stocks of goods; the travel to this place is increasing; the hotels and lodging houses are doing a good business; and in short, all the various business enterprises in this vicinity are gradually growing in importance, and we may safely predict that before many months the mining operation here will be extensive, and will support a large and flourishing town.

THE EUREKA (NEV.) SENTINEL says a diabolical attempt was made to kill Doc Hamilton the other day in this mine where he is working. He had drilled a hole about 10 inches deep, in which he left the drill. Upon returning to work next morning he found everything as he had left it, and he resumed work, but had only struck a few blows on the drill when a terrific explosion occurred. The drill was hurled from the hole with great force and broken in two, and Hamilton was struck and stunned by the flying fragments of rock. He was, however, not seriously injured, receiving only a cut on the ear and a severe bruise on the leg. Some fiend had inserted a stick of giant powder into the hole, and resploded the drill in order to give Hamilton no intimation of the murderous plot.

An absolute non-conductor of electricity has yet to be found, for all substances hitherto discovered are conductors of the force under certain known conditions; but those which offer a great resistance to it serve the purpose of non-conductors in practice, although they may all be classed as good or bad conductors. The best conductor at present known is silver; the poorest conductor is solid paraffine.

Postal Telegraph.

Why not postal telegraph as well as the old-time mail service? Why should the public enjoy the transmission of news, etc., at a nominal rate by train, and be forced to pay a private corporation a large rate by wire? That is the question, and the answer, in our opinion, is that the working of the telegraph at cost by the Government is just as much a needed contribution to the spread of intelligence to-day as the establishment of cheap mail service was years ago. It seems coming to that gradually. The probability is that we shall soon do much of our business and personal communication by lightning.

The present Postmaster-General is understood to favor the project, and various trade organizations have declared themselves as supporters of the demand for government telegraphy. It is not a new thing. It has been fully tried in England, and we are not therefore undertaking any visionary enterprise in adopting it. The English government bought the private telegraphs in 1869, and has extended them more than four fold since that time. The enormous increase in the value of the service to the public is, however, the chief feature. When the telegraphs were operated by private companies, rates were charged according to distance, and were very much higher than the rate established by the Government, which is one shilling, about 25 cents for 20 words besides date, address and signature to any part of the kingdom. With anything like the same ratio of increase in the use of the telegraph, it is evident that a higher rate would have yielded larger returns, which have inured to the public in this shape of reduced charges. The public was also benefited by the transmission of news, the number of papers served with telegraphic advice being increased from 173, in 1869, to 518, in 1880, the amount of news being largely increased, while the charge for this service was largely decreased. The private companies previously to the acquisition of the lines by government sent out about 6,000 words of news daily, when Parliament was in session, and 4,000 at other times. Under the government, 25,000 words of news per diem are sent when Parliament is in session, and 21,000 at other times.

In the United States our telegraph service, like that of operating railways, has been delegated to corporate organizations, and in the absence of proper supervision and control serious abuses have crept in, and the public has been taxed much higher for the use of these inventions (which it may be said have become necessities of commerce), than is necessary to yield a liberal return upon the capital actually invested. What this is may be indicated by the remarks of President Norvin Green, of the Western Union Company, at the last annual meeting of that company, Sept. 13, 1882:

The same rate of increase for the next five years will produce gross revenues of thirty-one and a half millions and net profits of sixteen millions per annum. But as the growth of the company has been in an increasing ratio—each five years showing a larger percentage of increase than the preceding five years—we may reasonably expect a still greater rate of growth, and, therefore, even larger figures for the year ending in 1887 than those above presented, enormous as they now appear.

It is estimated by good judges that there has never been paid in by stockholders \$16,000,000 since the beginning of the Western Union Company, and that its present property represents simply water and the amounts extorted from the public to extend its lines, besides paying dividends.

This great system, as well as the ocean cables connecting us with the rest of the world, are now virtually controlled by one man, and this individual, whose name has become a synonym for unscrupulousness and rapacity, in common with a few others with similar character, now aim at, and have largely succeeded, in controlling the channels of intelligence, of thought and of commerce, in a nation of 50,000,000 of people.

STILL ANOTHER "NEW USE" FOR ELECTRICITY.—A significant feature of the use of electric lights in agriculture, and one pregnant with great possibilities for the insect-tormented farmer, is the London *Globe* thinks, the wonderful inducement which the light offers to all sorts and conditions of insects to attempt multitudinous suicide by hanging their heads against the crystal globe all through the night and the small hours of the morning. A simple mechanical arrangement, in the shape of a grated trap, into which the impulsive creatures could fall, and whence they could not extricate themselves, would assist them to complete the happy work of self-destruction.

METALLIC GAS.—Some of our contemporaries are apparently making much of the alleged discovery of a Mr. John Dixon, of Liverpool, Eng., of what he calls "metallic gas." His process is merely a bungling way of making gas from petroleum, while he pretends the gas mainly arises from some hidden principle in various metals and minerals which he mixes with it—hence his title, "Metallic Gas." The scheme is merely the reproduction of an old deception practiced by the same party a year or two since in Sydney, where it was thoroughly exploded and shown up as a fraud.

MINUTE MICROSCOPIC MEASUREMENTS.—Mons. Perreux has constructed an apparatus for microscopic measurements which is capable of measuring 1-37,000th part of an inch. The instrument is so delicate that it can only be used at certain hours of the night when the jar of passing vehicles has ceased.

A Novel Way of Making Bullion.

W. P. Nye, well known among mining men as a skilled mechanic, returned last evening from the Plancha de la Plata mine, in Sonora, to which place he had been for the purpose of putting this prospect mill at that place in repair. The mill in question is but of two stamp capacity, although the engine and boiler attached have power for running double that amount. Mr. Nye states that from what he could learn while there the mine has enough ore in sight to run a twenty-stamp mill steadily for two years. The ore is marvellously rich in horn silver. About half a mile above the mill a number of Mexicans are taking out ore and reducing it by arrastras. The ore after being reduced to a pulp is then put into a large vat and boiled for a given time, at the expiration of which it is allowed to settle and the water taken off. The pulp when settled is taken out and the silver separated from it by means of washing it through a large wooden bowl, or, in plain English, "panning it out." While there Mr. Nye saw six and a half pounds of pure silver panned out of a pile of pulp about three feet in diameter and two feet high.

The process in use for the handling of the ore by the Mexicans at the place named is of a most primitive character, hars and shovels only being used in mining. The arrastras, as all mining men well know, are but a collection of large stones so arranged as to form a basin in which the ore is pulverized by the dragging of other stones over them, mules, oxen, horses or donkeys being the power employed for that purpose. The kettles or vats in which the pulp is boiled are made by the building together of strong, quite branches in the form required, and then cementing the sides exposed to the fire with a thick coating of clay. For the panning out process a large wooden bowl known as "the batea" is used. Crude as their means of working may be, the result is said to reimburse them largely for their labor.—*Citizen.*

The Location of Placer Claims.

A gentleman in Montana recently propounded the following questions to the consideration of the General Land Office at Washington:

1. Is an individual claimant limited to one location of twenty acres in a placer mining district?
2. What amount of work is necessary to maintain the possessory title to placer claims?
3. Can work performed or expenditures made in constructing a ditch for the purpose of working a placer claim be applied to the maintenance of possessory titles?
4. Does the law require a greater amount of work per annum to be performed by an association of eight persons to hold possessory title to a placer claim of 160 acres than it does of an individual claimant to maintain possessory title of twenty acres more? The official answer was as follows:

DEPARTMENT OF THE INTERIOR,
GENERAL LAND OFFICE,
WASHINGTON, D. C., Sept. 29, 1882
J. Walbridge, Esq., Bagges, Carbon County,
Montana:

SIR:—Your communication dated the 16th instant has been referred to this office. In reply to the inquiry therein contained, I have to state that the law imposes no limit upon the number of mining claims which a qualified person may locate. Eight persons are allowed to locate in one placer claim 160 acres. The amount of work necessary to maintain the possessory title to placer claims is left by Congress to be regulated by local laws and customs. In Colorado I believe the Legislature prescribes the amount. Whether work performed or expenditures made in constructing a ditch for the purpose of working a placer claim will apply to the maintenance of possessory title, is a matter that depends entirely upon local regulations and customs.

You will understand that a location by eight persons of 160 acres constitutes only one location or claim—not eight.

Respectfully,

M. McFARLAND,
Commissioner.

A NEW CARVING MACHINE.—A Michigan man has invented a new carving and molding machine that takes the palm for rapid work. In its construction the machine is very simple, being composed of a tool attached to a spindle that when thrown into motion springs up through an aperture in the table. The piece of wood to be carved or molded is then pushed against the tool, and the work is done quicker and better than any man could do it. The machine is designed to do all kinds of fancy carving work on cornices, moldings, newels and scrolls.

PAPER IN ARCHITECTURE.—An immense building is to be constructed in Chicago entirely of paper material. It will be six stories high, covering an entire block, and will contain 100,000 ft. of straw-board flooring, 480,000 ft. of straw ceiling, and a large amount of the same material for doors and counters.

A MASTODON GRAVEYARD.—The city of Dallas, Texas, is said to have a graveyard of mastodons, and for five or six years past excavations for buildings have seldom failed to bring up their bones. A large number of these mastodon remains were unearthed recently, and some of the bones were of enormous size.

THE ENGINEER.

THE SUBMARINE TUNNEL BETWEEN ITALY AND SICILY.—From the project presented to the Italian Ministry and proposed to the Venetian Society of Construction by Signor Gabelli, the following particulars are taken: The length of the submarine tunnel between Italy and Sicily will be 41,000 ft. The maximum depth of the sea above the line of tunnel is 365 ft. The thickness of rock between the roof of the tunnel and the bottom of the sea is 115 ft. The direction of the tunnel from St. Agata to Punta del Pizzo is almost due northwest to southwest. The two inclines descending to the tunnel will first run parallel with the shore and then descend to the lowest level by spiral tunnels. The length of these inclines is each 15,000 ft., and the area occupied by each spiral tunnel is 1,160 ft. The degree of inclination will be 35 per 1,000. The center of the tunnel will be on a higher level than the two ends. Walls and subsidiary tunnels will be constructed to drain off the precooling water, and the most difficult part of the line will be first commenced, which will at once show the geological construction of the ground and the difficulties to be overcome. According to the opinions of all geologists the bottom of the Straits of Messina consists of crystalline rock (granite, gneiss and mica schists). Neither in Calabria nor in Sicily can the upper strata that covers this crystalline rock be so thick as to reach the level of the bottom of the descending incline.

IMPORTANT ENGINEERING OPERATIONS.—Parts of Colorado, New Mexico and Arizona, in plats of hundreds of thousands of acres, are level and ready for the farmer, only that there is no water. The rivers running much higher than these valleys or table lands, offer abundant water for irrigation, provided that ditches or channels be cut and dams constructed to divert the water to them. There are numerous enterprises of this kind already in operation upon a moderate scale, and recently an English company has undertaken the cutting of a channel in central Colorado, which will render some 200,000 acres fertile and ready for the farmer's crops. Another stupendous undertaking of a similar kind is on foot by the Colorado Coal and Iron Company. This channel will be opened from a point on the Arkansas river 3½ miles below Canyon City, and be extended across the table-land in a southeasterly direction to the St. Charles river. The ditch will be 30 feet wide and 76 miles long, carrying 5 feet of water. Such enterprises are the feature of the new development of this new country, and are watched with a great deal of interest.

CHANGE IN DE LESSEPS' PLANS.—It is reported that the engineers of the Panama canal have made a radical change in their plan of operations. The intention of the projectors was to make a sea-level canal from one ocean to the other without locks of any kind. Information now comes out that they have found it impossible for any sum of money which could be raised to overcome the natural difficulties of such an undertaking, and they have decided to adopt the ordinary plan—that of locking, up and down the grades. The other scheme involved the operation of digging a canal for some distance through great cuts, which would have been several hundred feet deep, involving an amount of excavation the like of which was never attempted by human hands. There were other difficulties also in connection with that part of the canal where the bed of the Chagres river is utilized which the engineers concluded would form a fatal obstruction to the plan originally entered upon.

CONNECTING THE CHESAPEAKE AND THE DELAWARE.—The *Maritime Register* says: We notice that there is a movement toward carrying out the project of a ship canal between the Delaware and Chesapeake bays. The projectors of this new scheme say that this canal will be pushed to completion without asking for Government aid. This is a very sensible decision on their part. There is no reason why the Government should furnish the money for this work, and if it will give the great advantages to Maryland and Baltimore which have been claimed, Baltimore capitalists ought certainly to be able to build the canal.

RAILROAD IN CENTRAL AFRICA.—A party of 80 Frenchmen, assisted by 1,400 African laborers, are to begin the construction of a railway between the Niger and Senegal rivers. Their operations will be protected by a military column, which will plant the French flag and erect two forts on the Niger.

WORK STILL GOING ON.—It is stated that the works of the submarine railway between Calais and Dover are still going on, notwithstanding political objections, and the gallery is now 445 yards in length. Since the heading has been under the sea there has been, it is said, no leakage. Col. Beaumont's boring machine is being used.

FROM DENVER TO UTAH.—Track on the Utah Extension of the Denver & Rio Grande railway is now laid to Grand Junction, Col., 50 miles westward from the late terminus at Delta, and 425 miles from Denver. The new terminus is only 37 miles from the Utah line.

USEFUL INFORMATION.

SOME FACTS ABOUT BRICKS.—An average day's work for a bricklayer is 1,500 bricks on outside and inside walls; on facings and angles and finishing around wood or stone work not more than half of this number can be laid. To find the number of bricks in a wall, first determine the number of square feet of surface, and then multiply by 7 for a 4-inch wall, by 14 for an 8-inch wall, by 21 for a 12-inch wall and by 28 for a 16-inch wall. For staining bricks red, melt one ounce of glue in one gallon of water; add a piece of alum the size of an egg, then one-half pound of Venetian red, and one pound of Spanish brown. Try the color on the bricks before using, and change to light or dark with the red or brown, using a yellow mineral for buff. For coloring black, heat asphaltum to a fluid state, and moderately heat true surface bricks and dip them. Or make a hot mixture of linseed oil and asphalt; heat the bricks and dip them. Tar and asphalt are also used for the same purpose. It is important that the bricks be sufficiently hot, and be held in the mixture to absorb the color to the depth of one-sixteenth of an inch.—*Railroad Journal*.

EFFECT OF WIND ON DRAFT OF CHIMNEYS.—In a paper bearing the above title, and which was recently read at Southampton, England, by Lord Rayleigh, it was stated that a horizontal wind would usually promote a draft, except in cases where the chimney opened out upon a large expanse of wall, and so was indirectly affected, in which case there was only one cure, namely, to carry the chimney higher. When the wind was inclined downward to the chimney at an angle of 30° and more, there was a down draft, and the maximum up draft was produced by wind inclined upward at about the same angle. The simplest thing to prevent wind blowing down a chimney was to erect a T-piece on the top. In that case a vertical or inclined wind favored the draft, and the effect of a wind blowing through the T tube was practically nothing. Lord Rayleigh, moreover, contended that chimneys should be turned upside down; that is, the opening at the fireplace should be narrow and the outlet wide; and that if all the chimneys in a house could be made to open into a common cloaca, a down draft would hardly ever occur.

A FOUNDRY FLOODED WITH SULPHUR.—A singular and remarkable occurrence recently took place in the large foundry of the Reading, Pa., Hardware Company, where 90 men are employed. The atmosphere on the outside was dense and all the windows were tightly closed. Suddenly a large amount of sulphur and gas was driven out of the opening in the cupola among the men, scattering all over the foundry. Ten became deathly sick and dropped to the floor at once. The others commenced vomiting and complained of severe pains in the stomach and head. Two were perfectly unconscious and remained in that condition for some time, having to be taken to their homes in carriages. The foundry presented the appearance of a huge hospital, with men lying in every direction. About 70 men were affected.—*Ex.*

THE PROTECTIVE QUESTION.—A great deal of needless misunderstanding is occasioned in protection-free-trade discussions by not understanding terms and phrase. A high tariff is not necessarily a protective tariff, nor a low one for revenue. Protection is an end to which a tariff is the means, and this end may be secured, sometimes by a high tariff, sometimes by a low tariff, sometimes by no tariff at all. An exceedingly high tariff may not be obstructive after it has ceased to be protective. The duty on horse-shoe nails, for example, is very high and practically inoperative, but it is in no sense obstructive. A high tariff, when inoperative, is also obstructive only when it prevents competition and makes monopoly possible.—*Boston Com. Bul.*

POTENCY OF THE HUMAN VOICE IN CONTROLLING THE HORSE.—The reins may guide the horse, the bit may inspire him by its careful manipulation, and the whip may urge him forward to greater ambition; but the human voice is more potent than all these agencies. Its assuring tones will more quickly dispel his fright; its severe reproaches will more effectually check his insubordination; its sharp, clear, electric commands will more thoroughly arouse his ambition, and its gentle, kindly praises will more completely encourage the intelligent road horse than the united forces of the bit and reins and the lash. No animal in domestic use more readily responds to the power of kindness than the road horse.—*National Live Stock Journal*.

HOW TO TELL A GOOD MILLSTONE.—An old Hungarian miller is reported to have given this rule for telling a good millstone: "When about to select a stone take a flask of gin and pour a little of it upon the stone; if the stone absorbs the liquor so that the surface appears dry, it is a good one, but if the gin remains on the surface the stone is good for nothing."

THE MINT IN SAN FRANCISCO is the largest in the world—twice as large as the one in Philadelphia, and three times the size of any in Europe, having \$24,000,000 worth of coin and bullion stored away in its vaults.

PROGRESS OF MANUFACTURING INDUSTRY.—The progress of manufacturing industries in the United States has been such that an arbitrary division into manufacturing and agricultural sections can no longer be maintained. In seven principal Western States—Ohio, Indiana, Illinois, Missouri, Iowa, Wisconsin and Minnesota—the manufacturing industries were less than one-half those of the New England States in 1850. Now these industries in the Western States named exceed those of the New England States. More than 10 years ago the annual aggregate value of manufactured products exceeded the value of all agricultural products in the above Western States. The number of patents now annually taken out in the North-western States far exceeds the number issued to citizens of the New England States.

THE SPRING STREET CAR MOTOR.—It is reported that recent experiments in Philadelphia have proved that it is possible to propel street cars smoothly and rapidly by the expansion of powerful steel springs, the difficulty of giving a uniform and perfect temper to the metal having been overcome. The company controlling the patents makes the following claim: The motor consists of six springs coiled upon a cylinder. Each spring will be made of a flat bar of steel 300 ft. long, 6 inches wide, and one-fourth inch thick. These springs are tempered by the new process so uniformly and delicately that their power becomes tremendous. After first being coiled so that their diameter is 18 ft., they are tempered, and then wound up until the diameter is 7½ ft. In this condition they are placed upon the motor truck and the appliance of the patents adjusted.

SUBWAYS FOR GAS AND WATER PIPES.—The *New York World* suggests the advisability of constructing under the streets of that city what it calls subways, through which working men can travel, as a means of avoiding the tearing up of streets for the repair of water, steam and gas pipes. This is by no means an infeasible scheme, since it has long been in operation in Paris, and for a city so troubled with travel and traffic as New York there are few greater nuisances than an uproot street. In time this difficulty will come to perplex us, after we have solved our bridge problem.

THE ERIE CANAL was formally opened in 1825; it then carried a boat through with 90 barrels of flour; now 900 barrels are the regular cargo.

GOOD HEALTH.

The Digestibility of Oysters.

Why oysters should be eaten raw is explained by Dr. William Roberts in his lecture on "Digestion." He says that the general practice of eating the oysters raw is evidence that the popular judgment upon matters of diet is usually trustworthy. The fawn-colored mass, which is the delicious portion of the fish, is its liver, and is simply a mass of glycogen. Associated with the glycogen, but withheld from actual contact with it during life, is its appropriate digestive ferment—the hepatic diastase. The mere crushing of the oyster between the teeth brings these two bodies together, and then the glycogen is at once digested without any other help than the diastase. The raw or merely warmed oyster is self-digestive. But the advantage of this provision is wholly lost by cooking, for the heat immediately destroys the associated ferment, and a cooked oyster has to be digested, like any other food, by the eater's own digestive powers.

"My dear sir, do you want to ruin your digestion?" asked Prof. Houghton, of Trinity college, one day, of a friend who had ordered brandy and water with his oysters in a Dublin restaurant.

Then he sent for a glass of brandy and a glass of Guinness' XX, and put an oyster in each. In a very short time there lay in the bottom of the glass of brandy a tough, leathery substance resembling the finger of a kid glove, while in the porter there was hardly a trace of the oyster to be found.

CITY SEWERAGE.—In answer to a question recently, when before a committee of the City Council of Philadelphia, Col. Waring said, with reference to the ventilation of sewers: "I would use neither street openings nor tubes. Each householder should be required to run the drain pipe which carries the sewage from his house up to the roof. It should be left untrapped, and then every discharge of sewage all through the city would be followed by a draft of fresh air. With such sewers as yours the impregnation of the soil by noxious gases is much to be feared. It would cost little more to make them fit to do the duty for which they are designed. They should be gasketed inside and out, the joints tightly closed and the material of the heat, and they should be kept clean. But defective house drainage exerts influences as harmful as do the most wretched sewers. The greater number of the cases which doctors attribute to sewer gas is due to fault, not in the sewers themselves, but to the filthy pipes which carry off the house drainage. Illuminating gas very often escapes from the pipes into the sewers, and most of the explosions are apparently due to that cause."

Salicylic Acid in Typhoid Fever.

A member of the French Academy of Medicine, at Paris, M. Vulpian, at a recent meeting of the Association asked if the terrible scourge of typhoid fever might not be more successfully treated by the employment of some soluble antiseptic, susceptible of finding its way, without alteration, into the intestines, and then neutralizing the typhoid virus. Trial in that direction had been made with various antiseptics, but salicylate of soda seemed to have been attended with the best results.

M. Vulpian, recalling the fact that typhoid fever, the same as the small-pox, the measles and scarlet fever, consists in reality of an intoxication caused by the virus absorbed, and which, on its first attack, we seek to combat in the blood itself and in its organic elements, remarked that the medicine ought to reach not only the microbes but the nervous centers, which impel the general circulation.

To effect this, his choice is salicylic acid, to which numerous German, Italian and American works have for a long time accorded an action certain and preponderant.

The dose of salicylic acid—given in unbleached bread—is about half a gramme every half hour or hour, but it has been increased successfully to 6, 10, and 12 grammes—one gramme is equal to 23 grains. It is the medium dose of 6 to 7 grammes per day which should form the base of the new medication.

From a careful study of various cases at the Hotel Dieu, it is found that but little inconvenience is experienced in administering salicylic acid; while on the other side, the beneficial effects of salicylic acid have always been very striking, as follows:

The regular and permanent lowering of the temperature from 40.5°, to 39°, 38.5°, at the end of 24 hours. Amelioration of the general condition of the patient.

The action of this medicine is, then, logical, though it may not be all-powerful and veritably curative. Salicylic acid, given in sufficient doses, is, up to this time, one of the most powerful agents in moderating typhoid fever.

This point established, M. Vulpian demanded, "if salicylic acid could not be employed as a prophylactic and preventive agent in epidemics of typhoid fever, and if taking daily a moderate dose of the medicine would not have the effect of annihilating the action of the typhoid poison?"

THE ASHES OF THE DEAD.—A correspondent of *Knowledge* (London), who signs himself "A Brother Cinder," referring to the first two cremations which have taken place in England in modern times and to the disposition which was made of the ashes, begs leave to suggest "a far neater and more appropriate mode of disposing of the ashes of a corpse cremated. These ashes, I think," he observes, "consist wholly or principally of phosphate of lime, and therefore have only to be treated with sulphuric acid to convert them into sulphate of lime—i. e., gypsum of plaster of Paris. With this substance a model can be cast in a mould previously prepared, and representing either the full figure of the deceased or simply the bust, or the likeness can take the form of a medallion. Whichever form of memorial is adopted a glass case would be sufficient protection for it, and the costly urn can be dispensed with as unnecessary, while the remains of our loved ones will themselves be gathered into the form of a compact and lifelike memorial, which itself will be composed of the veritable 'ashes of the dead.'" It is doubtful whether in this country, for years to come, if ever, the idea of incineration or cremation can be popularized. There is a repugnance to it in the general mind which cannot easily be overcome. In France the subject is in a manner forced upon the public. The crowded condition of the cemeteries necessitates the removal of bodies long distances from the city—as much as 30 miles—the expense of which, when the poor are interred, falls upon the municipality. In consequence a bill is before the Assembly to legalize cremation. In England also this question of cremation is being seriously considered. The same argument applies to London as to Paris in reference to disposing of the remains of the dead. England will be slower to accept the alternative than France, but it would not be surprising if both countries would ultimately adopt it, as the least of evils presenting themselves in connection with sepulture.

POWER OF THE WILL.—We hear frequently of pretenders who profess to heal diseases by "laying on of hands," etc. The real manner of healing in all such cases is merely the determined exercise of the will power, or what is the same thing, faith in the healer and his art. Witness the following evidence of the power of the will in such cases: A lady was sick from apparent exhaustion, and for a long time had kept her bed. Her pastor, at her request, had prayed and prayed, but she was no better. A new physician one day called. He came to her bedside and said: "I think that the best thing you can do is to get up!" And she got up. "Go down stairs!" And she went down. The next day she was on the street, enjoying a walk after a long, long confinement. "I didn't cure her," said the physician, "for there was nothing to cure. She had lain in her bed so long that her will power had all gone." His prompt and heroic treatment startled into life her paralyzed resolution.

 Dividend Notice—Stannard Con. M. Co., S. F.

Passing Events.

We begin with this number Volume XLVI of the MINING AND SCIENTIFIC PRESS under encouraging auspices, the paper now having a large and increasing circulation and liberal advertising patronage. We intend to make this volume exceed its predecessors, and more particularly in respect to the illustrations, which will be more numerous than formerly. The PRESS will be improved in every way, and our patrons may rest assured their interests will be closely looked to.

News from the mines is somewhat meager just at present, the weather of late somewhat interfering with operations.

The most notable local event of late has been the unprecedented fall of snow in San Francisco, Oakland and many other towns in this State on December 31st. Never since the State has been an American one has a similar storm occurred in the coast regions. The snow-fall was four to six inches deep, and thousands of persons saw snow for the first time.

There came near being a bad fire in the Sutro tunnel on New Year's day. It took about three hours to drive the smoke back, the fire being at a point 300 ft. north of the C. and C. shaft, but when the fire was finally reached it was quickly extinguished. It burned about 13 sets of timbers and the drain boxes that ran along the side of the drift. No great damage was done.

Magnetic Separation of Ore.

Some time since we illustrated and described the apparatus invented by Mr. Edison for the magnetic separation of ore. A man named Hans J. Muller, of New York, has now invented one of an improved form. The new machine consists of a revolving cylindrical electro-magnet, around which a band or belt passes, also passing around a cylinder or roller parallel with the magnetic cylinder in combination with a vibrating feeding device, from which the granulated or pulverized material drops tangentially to the magnetic cylinder, so that the particles of steel or iron will be attracted by the magnetic cylinder and will be carried off by the belt until the same leaves the magnetic cylinder, when these particles of iron or steel will drop into a suitable chute or receptacle separated from the box or chute into which the ore drops by a beveled longitudinal partition.

A magnetic plate extends longitudinally along the magnetic cylinder, below the same, and over the chute into which the particles of iron drop, for the purpose of preventing the swinging clusters or particles of iron or steel which are formed on the belt from dropping into the chute or receptacle from the ore. The invention also consists in so constructing the magnetic cylinder that it has double poles—that is to say, two opposing poles in the middle of its length, beside those at the ends.

For very finely divided particles the belt is made of thin sheet brass, but for coarser particles it is made of steel or iron sheets.

The operation of the machine is as follows: The pulverized ore from which the particles of iron or steel are to be separated is placed in a hopper, and the cylinder is rotated. By suitable mechanism a shelf is vibrated on a horizontal plane, and the non-metallic portion of the pulverized ore, or rather the portion which has only slight capacity for magnetic attraction, will drop from the inner edge of the shelf through a slot. As the material passes the cylinder the particles of iron and steel will be attracted by the magnetic cylinder and will cling to the belt and be carried around by the same until it leaves the cylinder, which takes place directly above another slot, when the particles of iron or steel will drop into or through a slot into a receptacle. The ore leaves the belt at this point because the magnetic attraction there becomes insufficient to hold it—to support its weight.

In case the pulverized ore contains very large quantities of iron or steel, long clusters or particles of iron or steel will be formed at the lower part of the cylinder, and as these clusters receive a swinging motion from the movements of the belt, they drop sometimes, but arrangements are made to catch them.

Classification of Mineral Lands.

The method of classification of mineral lands on the public domain when the lines of the survey are being extended over them is as follows: At the time of survey in the field the deputy Surveyor notes on his field notes (which remain permanently in the Surveyor-General's Office, a copy being sent to the Commissioner of the General Land Office) the character of the country, both from observation and information from persons, if any there be having knowledge of the same. This makes up the general topography. He describes the country by sections one mile square. When the deputy makes up his plats he enters upon them the topography noted in his field notes and returns the same to the Surveyor-General, who prepares three copies thereof. One of the township plats, with a copy of the field notes, is sent to the General Land Office to be used in checking all entries or changes of entries made in the district land office. If the land surveyed is returned as mineral, the Commissioner at once issues notice to the land office of the district in which the lands lie of the withdrawal of the same from agricultural or entry other than as mineral. Claimants of mining claims may make application for survey to the surveyor-general, as provided by law, and the survey of their claims will be made by a mineral deputy, with or without reference to the lines of the rectangular system. Still they can and may be used for points of determination and reference. Proof is admissible upon contest in the district land offices between claimants as to its mineral or non-mineral character. The Register and Receiver render an opinion on the case, which is forwarded to and approved or disapproved by the Commissioner of the General Land Office, and after his action is subject to appeal to the Secretary of the Interior. In case the rectangular surveys are not extended over the lands containing mineral, the claimant, whether a mining district has been formed by the miners or not, applies to the Surveyor-General, who orders a survey by a deputy mineral surveyor whether public land surveys have been made or not. The survey of a mining claim—lode, vein or placer—has no reference necessarily to any other surveys or systems of surveys.

Academy of Sciences.

Annual Meeting and Election.

The annual meeting of the California Academy of Sciences was held on Monday evening last, President Davidson in the chair. The report of the election held during the day was read and showed the following result: President, George Davidson; First Vice-President, Justin P. Moore; Second Vice-President, H. Herman Behr; Corresponding Secretary, Samuel B. Christy; Recording Secretary, Charles G. Yale; Treasurer, Elisha Brooks; Librarian, Carlos Troyer; Director of Museum, W. G. W. Harford; Trustees—George E. Gray, Ralph C. Harrison, James M. McDonald, Robert W. Simpson, Thos. P. Madden, Charles F. Crocker, Lewis Gerstle.

Financial Condition.

The Board of Trustees of the Academy submitted a report showing the financial status of the Society: The total amount of receipts for the year from all sources has been \$28,445.14; total expenses, \$25,707.04, leaving a balance cash on hand of \$2,829.17. In April the Trustees purchased from Professor Henry A. Ward a valuable collection of natural history, paleontology and geology, for \$16,000, and placed it in charge of the Director of the Museum to be opened for public exhibition at Mercantile Library Hall, which was hired for the purpose. Messrs. Charles Crocker and ex-Governor Leland Stanford donated \$8,000 each to enable the Academy to effect this purchase, and the joint gift is now named the "Crocker-Stanford Collection." The amount collected for dues and memberships from life and resident members during the year was \$3,257.50; outstanding monthly dues, considered collectable, \$998.50; rents yielded \$1,118.44, while payments of all kinds aggregated \$2,333.75. The property of the Academy consists of the library and museum, with its fixtures and furniture, bookcases, desks, safe, specimens of mammals and birds and the Crocker-Stanford collection.

The real estate owned by the Academy is described as follows: Market street, lot lying on the southeast line of Market, 195 ft. southwest from Fourth, thence southwest 80 ft., thence southeast 275 ft., thence north 113 ft., thence northwest, 195 ft. to point of beginning (the gift of the late James Lick during his lifetime). The title is now perfect. City lot between Geary and Post streets, 187 1/2 x 240 ft., corner of First avenue and Meade street. Other permanent property to the value of \$274.80 was also acquired by purchase during the year. There is in process of settlement a half interest as residuary legatee in the unsettled estate of James Lick, likely to be realized by the close of the year 1885. In August Mrs. E. B. Crocker, of Sacramento, donated a rare and valuable collection of over 1,000 birds and 100 mammals in glass cases, valued at \$12,000. Patrons of science have donated gifts to the amount of \$32,058.50.

A valuable paleontological collection, purchased by Irving M. Scott, Wm. B. Hyde, Jas. O'B. Gann, Christian Froelich, Jr., R. H. Pease, Jr., Andrew Carrigan, P. N. Lilienthal, J. B. Randol and A. Chahot, has been donated to the Academy, and is now on exhibition at Mercantile Library Hall. This was purchased from C. D. Voy, and is known as the Voy collection. The Trustees have in charge as a special trust the "Crocker Scientific Investigation Fund," which consists of 20 registered bonds of the Southern Pacific railroad for \$1,000 each, and the income is being regularly expended in assisting worthy investigators in accordance with the terms prescribed in the letter of Charles Crocker, the generous donor of the fund. Henry M. Newhall, a late fellow member, generously, as a donation, advanced the sum of \$300 from the rent of the building. The executors of the estate have reduced the rent to \$150 monthly. During the year the Board of Trustees held 34 meetings. A special committee, appointed to consider the propriety of removing the museum of the Academy to some more suitable locality, failed to find a desirable building in a proper neighborhood. The sum of \$3,430 was collected from 25 subscribers to provide a fund necessary to maintain the free exhibition of the Crocker-Stanford collection at Mercantile Library hall.

Officers' Reports.

The report of the Recording Secretary, Chas. G. Yale, showed that there had been elected during the year 40 resident members and 23 life members; deducting resignations, dropped for non-payment of dues and four life members who died, there was a net gain during the year of 47 members. There are now 118 life members and 188 resident members, or 306 in all. Twenty-five meetings of the Academy were held during the year, 24 being regular and one special. The average attendance at meetings during the year has been 51.

The report of Elisha Brooks, Treasurer, showed the following items: Receipts, gifts, etc., \$19,758.30; interest of Crocker's Scientific Investigation Fund, \$1,200; from rents, \$4,118.44; from life memberships, \$1,800; dues from resident members, \$1,457.50; sundries, admission to museum, etc., \$1,070; balance on hand January 3, 1882, \$91.07. Total receipts, \$28,536.21. Disbursements—Maintenance Fund, \$17,876.47; Crocker's Scientific Investigation Fund, including allowances made, \$720; expenses investigating the Carson footprints,

\$103.15, \$823.15; General Fund, rent of halls, and all other expenses, \$7,007.42. Total, \$25,787.04, leaving a balance in bank of \$2,829.17.

The report of the Librarian, Carlos Troyer, shows 843 volumes of valuable works received, besides the usual exchanges. All authors issuing pamphlets on subjects of interest throughout the Pacific coast are requested to donate a copy for preservation in the Academy's library.

Mr. Haaford, Director of the Museum, gave an ennnary of the donations to the museum for the year.

Honors to Members.

The Council of the Academy, acting under the privilege allowed it of nominating for life membership two members annually, presented the name of Gustaf Eisen, a young man who has done of late some very valuable scientific work in the investigation of "Earth Worms." He has contributed many botanical specimens to the Academy, and as a natural history student stands in the front rank. The Council's recommendation was adopted, and Mr. Eisen was unanimously elected.

Vice-President J. P. Moore stated that one of our oldest and most valuable members was about to leave us to pursue scientific work at the Smithsonian Institution, in Washington, and he thought that the Academy should take some suitable action in expressing its appreciation of his services and labors while with us and wish him Godspeed on his journey. He alluded to Dr. Robert E. C. Stearns, who was well known to all the members as one of our earnest workers and most intelligent co-laborers. Professor Davidson, the President, heartily coincided with the views expressed by Mr. Moore. He said the scientific work done by Mr. Stearns in his specialty was recognized as of the highest value. He had been one who had always kept in view the highest interests of the Academy, and had been identified with it for many years. The Board of Regents of the University of California, a very conservative body, had on his resignation of his long held position of Secretary of the Board, conferred on him the degree of Ph. D., an honor of which they are very chary. The President thought a committee should be appointed to draft suitable resolutions expressive of the regret of the Academy at Dr. Stearns' departure. A motion to that effect having been made, J. P. Moore, H. W. Harkness and Dr. A. Kellogg were appointed.

Mr. Moore spoke of the valuable botanical and arboral work done by Dr. Albert Kellogg, under the patronage of the "Crocker-Stanford Scientific Investigation Fund," which he characterized as unsurpassed for beauty of execution and thoroughness of detail. Dr. H. W. Harkness has labored constantly at his work on Fungi, assisted by Mrs. Dr. Curran. This new department of Fungology, now being paid so close attention to, was very important, and the labors of Dr. Harkness were of the greatest degree of value.

Transit of Venus.

Prof. Davidson asked for one month's further time to prepare his report, as his time had been fully occupied since his return from observing the transit of Venus. He then gave a rapid sketch of his astronomical observations and the mechanical details of the transit party, with free-hand blackboard illustrations. The Professor described the peculiarities of the transit in detail, and gave a very interesting lecture. He said his party were favored with exceedingly clear and fine weather, and the contacts were sharp and clear, no "black drop" or wavy outline being apparent. He spoke of the peculiar halo, or light, on part of the planet. He said two new observers, not professionals, Mr. J. P. Moore, at Mt. Diablo, and Mr. Burkhalter, in Oakland, had observed a flash of light on the planet when it left the sun, not noticed by any other observers. Mr. J. P. Moore described the transit as seen by him from Mt. Diablo.

California State Geological Society.

The sixth annual meeting of the California State Geological Society was held Thursday, Dec. 28th, at the rooms of the State Mining Bureau.

The President read his annual address, which we have put in type, and will publish in full in next week's PRESS.

Henry Janin, M. E., Louis Janin, M. E., Hon. John Daggett, John D. Coughlin, D. W. C. Morgan, L. Wagoner, M. E., Jas. H. Croseman, Hon. Jos. Wagoner, Chas. G. Yale, W. B. Ewer and J. R. Scupham were elected regular members, and Dr. Joseph Szabo, of Budapest, Hungary, was elected a corresponding member. A paper by James H. Croseman, describing Santa Fe mining district, Emeralds, Nev., was read by the Secretary.

The election of officers for the ensuing year resulted as follows: President, Henry G. Henke; Vice-President, Melville Attwood; Secretary, S. Heydenfeldt, Jr.

IMPORTANT TO MINERS.—The Supreme Court of this State has recently rendered a decision to the effect that the law of Congress requiring an annual expenditure of \$100 on unpatented mining claims apply to gravel and placer claims as well as quartz. It has usually been considered that the law was intended for quartz claims only, but owners of all kinds of unpatented mining ground have now a warning that it is important that they shall heed, and if the requisite amount of work has not been done within the past year, they should be prompt in commencing the labor now at the opening of the new year.

The State Mining Bureau.

Report of the State Mineralogist.

The report of State Mineralogist Hanks has been laid on our table this week, and while no very careful review is possible, we find much of interest. The report fills 288 pages, with an appendix of 266 pages, and there is also a catalogue of 349 pages, showing the specimens given to the Bureau during the year ending April 16, 1881. The report itself covers a period of two years. The following figures will show the growth of the institution:

Receipts from Dec. 1, 1880, to Sept. 1, 1882, total, \$15,432 46. Total warrants issued from Dec., 1880, to June 1, 1882, \$20,888 65. Complete tabulated statements of all transactions are embodied in the report. In addition to a fine collection to start with (all of the State Geological Society's accumulation), there have been added between Dec., 1880, and Sept. 1, 1882, 723 books and pamphlets, 66 maps, charts and pictures and 2,124 specimens of minerals, as follows:

Donated—Books and pamphlets, 682; maps, charts, etc., 39; minerals, etc., 1,904; total, 2,565.

Purchased—Books, 102; maps, etc., 27; minerals, etc., 220; total, 349; grand total, 2,914.

This, added to the previous collection, which consisted of—books and pamphlets, 433; maps, charts, etc., 61; minerals, etc., 2,023; total, 2,517, presents a grand total of 5,431 catalogued and prepared for exhibition. There is still a large number of mineral and other specimens not yet catalogued, of which no record is made. Mr. Perkins, the Secretary, adds the following interesting information on an important feature of the Bureau: Since the date of the last report 1,090 letters have been written to 1,023 correspondents, as follows: Communications and replies on sundry subjects, 563; acknowledgments, 195; information on minerals, 151; information, various, 175; total, 1,090. During the same period there were received 900 letters from 659 correspondents, as follows: Sundry subjects, 186; acknowledgments, 91; inquiry on minerals, 96; inquiry, various, 206; donations, 98; information, 223; total, 900.

The principal paper in the report is on Placer, Hydraulic and Drift Mining, by the State Mineralogist. He also has a paper on Ores and Iron Industries of California. There is also a chapter on "Lumber and Fuel," one on "Salt in California," one on "Mud Volcanoes in the Colorado Desert," on "Diamonds in California," "Notes on Mica," "Notes on Roscoelite," "Diatoms and Diatomaceous Earth." There is also a glossary of mining terms, compiled by Dr. De Groot. There is also in the chapter on hydraulic mining some copious notes on gold, and tables of yield of California gold mines.

The appendix contains several papers supplementary to the Report of the State Mineralogist. The most exhaustive is on "The Forest Trees of California," by Dr. Albert Kelllogg. We have published a number of descriptions from this part of the report, which formed part of a separate publication printed some time since. "Notes on Hydraulic Mining" is a paper by F. W. Robinson. "Hydraulic and Drift Mining" is by Dr. Henry De Groot. "On the Milling of Gold Quartz" is by Melville Allmar.

"Rare Minerals Recently Found in the State" is by Wm. P. Blake. "Fluoride" is by Almarin B. Paul.

The following remarks by the State Mineralogist show the growth of the museum: "A catalogue of the first year's collections, amounting to 3,000 in number, has been prepared and is ready for distribution. The number of specimens entered and ready for the museum is now 4,147, and there are at least 2,000 more not so entered, but in process of classification. The museum is growing more rapidly than is generally known or could be expected; specimens are flowing in from every part of the State, and also from other States and Territories of the Pacific

coast. Besides these, many valuable specimens have been obtained in exchange with other States of the United States with foreign countries.

"Duplicate Specimens.—In making the collections many duplicates have been collected. To these have been given the same numbers received by the specimens in the museum cases. It is the intention of the management to place these duplicates in suitable drawers in which they will be accessible, and to make up sets for

it is also true that, with a few trifling exceptions, no money has been expended beyond furnishing cases and paying necessary freight; nor in any way has the legitimate working of the Mining Bureau been interfered with by this cause. The popularity of the institution has stimulated the generosity of citizens, and the State Museum has been greatly enriched by these donations. The policy of the State Mining Bureau was set forth in circulars issued and published in the first report of the State

Winter at the Seaside in California.

It is only upon the Pacific coast that seaside scenes are a delightful year round. Winter on the Atlantic coast is most dreary, and the various resort hotels stand deserted upon lonely wastes. It is quite different in California, for winter at the seaside is even more delightful than summer. The greater part of the time the sunshine is warm, the air clear, the fields and gardens full of beauty and fragrance, and the whole scene is in perfect contrast with the "winter" as it is known in all other parts of the country.

There are several seaside places which are truly entitled to distinction as winter resorts, but the most prominent just now is Monterey, with its splendid hotel and its handsome grove and well-kept gardens. Our engravings give glimpses at some of the charms at Monterey. One of the pictures is a view of the Hotel del Monte, which was built in 1880, and is without question the handsomest watering place hotel in America. The site selected was in a lovely grove of pine, oak and cedar, the trees being sufficiently scattered to admit of the adornment of the grounds by means of drive-ways, foot-paths, lawns and beds of flowers. A plot of 126 acres was enclosed and set aside as the hotel grounds, while 7,000 acres more were purchased for other purposes. The fact that the visitor may ride a score of miles over well-kept macadamized roads, and be nearly all the time within the borders of the hotel company's property, serves to show in some measure the vast extent of these possessions.

The Hotel del Monte is constructed in the modern gothic style, and cost, with its furniture and other appointments, a quarter of a million of dollars. No seaside hotel upon the Atlantic coast can approach its plan of exterior, while its interior design and finish display the same refined taste and lavish use of wealth.

Another engraving gives a scene in the park surrounding the Hotel del Monte. The picture is from a photograph taken by Watkins, in January, 1882, and thus gives the grounds in their true winter condition. The evergreen oaks, the fresh grass, the blooming plants in the borders show how gentle is the air and warm the winter's sun. In its beautiful embellishment of foliage and flowers, the Hotel del Monte resembles some rich private home in the midst of a broad park. This impression is heightened when the broader extent of avenues, lawns and flower-bordered walks come into view. The gardener's art has turned many acres into a choice conservatory, where the richest flowers blossom in profusion. Here and there are swings, croquet plat, an archery, lawn-tennis grounds and bins of fine beach sand, the latter being intended for the use and delectation of the children who cannot await the bathing hour for the daily visit to the beach. In all directions there are seats for loungers, and the situation and arrangements are in every way delightful.

GOLD COIN MADE HERE. Coinage operations at the Mint in this city for the year 1882 were confined to gold coin and standard dollars, as follows: Double eagles, \$24,175 000; eagles, \$2,820 000; half eagles, \$1,670 000; standard dollar, \$9,250 000; total, \$37,915 000. The largest amount of coinage for the year was in August, when \$6,130,000 was made, including \$5,180,000 in double eagles and \$950,000 in standard dollar. The amount of standard dollars coined last year is \$3,510,000 less than in 1881. This decrease is due to the inability to procure fine silver for the Mint here on as favorable terms as at the other Mints. The total coinage for 1881 was \$11,845,000, and for 1880 it was \$37,427,000. There was comparatively little small gold coined last year. In 1881 there was \$9,700,000 in eagles and \$4,845,000 in half eagles.

HOTEL DEL MONTE, AT MONTEREY, CAL.—VIEW OF THE WEST SIDE.

the use of the public schools, and to be used in exchanges. Application has already been made by the State Normal Schools, and, as soon as possible, selections will be set aside from the duplicates for these institutions. Application was also made by the dental department of the State University for a set of minerals to illustrate hardness of minerals, which was furnished as requested.

"The establishment of the State Mining Bureau has developed, or rather made manifest, the

Mineralogist, from which no deviation has been made, except when forced by the diminishing Mining Bureau fund."

As we have said, it has been impossible in the limited time to go into any extended review of the report; but it appears a creditable document, and one that will be of interest to the mining community for whom it was written. It is to be hoped that it will be circulated in this State, which pays for it, and not be too freely scattered elsewhere, as seems to be the

SCENE IN THE GROUNDS OF THE HOTEL DEL MONTE, FROM A PHOTOGRAPH IN JANUARY.

want of a first-class chemical and metallurgical laboratory, in which analysis of ores, minerals, mineral waters, rocks, building stones and other mineral deposits of the State should be made, and the results published for the benefit of the people of the State directly and the world at large indirectly.

With regard to the nature of the collection Mr. Hanks says: "It has been intimated that the Mining Bureau has paid undue attention to the collection of curiosities and specimens of natural history, and, in doing so, has overstepped the intention of the Mining Bureau hall. While it is true that many valuable donations of this character have been received,

fate with U. S. Mining Commissioners' and Mint Directors' reports, few of which reach the people for whom they are intended. Our legislators, when they get these reports, should look to it that representative miners in their localities obtain them.

The Old South Church of Boston has called Rev. George A. Gordon, of Greenwich, Conn., at a salary of \$8,000 and the parsonage.

LEAD in Liverpool is quoted at £14 to £14 24. 61. for English, and £13 15s. per ton for Spanish, with and without silver.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. P. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. **HALLIDIE IMPROVED ORE TRAMWAYS.** We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

—OR—

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal.

A machine can be seen in working order, and ready to make tests, at the office of Hincley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That it has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for. That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

LEFFEL'S WATER WHEEL,

The "Old Reliable,"

With Important Improvements, making it the

MOST PERFECT TURBINE NOW IN USE,

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for New Prices, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO.,

Springfield, Ohio, and 110 Liberty Street, New York City.

PARKE & LACY, Sole Agents, 21 and 23 Fremont St., S. F.

THE MOREY & SPERRY MINING MACHINERY CO.,

Successors to MOREY & SPERRY,

Manufacturers of all kinds of

MINING MACHINERY.

Gold and Silver Grinding, Concentrating and Amalgamating Machinery, Engines and Boilers of any size. Hydraulic Giants, Hydraulic Outfits. All the various kinds of Amalgamating Pans, Combination, Eclipse, Excelsior, etc. Settlers, Rock Breakers. Stamp Mills for Wet or Dry Crushing. Howland's Pulverizer, Improved Rollers.

Retorts for Gold and Silver, Silver Plated Copper for free Gold Amalgamation. Hoisting and Pumping Machinery, Chloridizing Furnaces, etc. Mining and Mill Supplies of every description. Steel Shoes and Dies that last three times as long as any iron.

WAREROOMS: 92 & 94 Liberty St., New York.

Foundry and Machine Shop: Newburg, N. Y.

NOTICE.—The public and former friends and patrons of the old firm of Morey & Sperry are hereby notified that the above-named Company is the legitimate and ONLY successor to the said firm, having acquired all the drawings, patterns and machinery of the old firm, together with the lease and good will of its business.

We shall continue the business, with largely increased facilities, at the old place, having made connection with the Newburg Steam Engine works, which have been enlarged to meet the demands of this Company. Mr. Franklin Morey, of the late firm of Morey & Sperry, will manage the business of this Company. Mr. Franklin Morey, of the late firm of Morey & Sperry, will manage the business of this Company. Information and estimates and Workmanship First-Class.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

A New Fire Extinguisher.

We examined this week, at 409 California street, a new form of fire extinguisher presenting several novel and improved features which make it a very superior apparatus, overcoming the objections to the old forms. The extinguisher, as the cut represents, is a double tank made of galvanized iron or brass, each tank holding three gallons of water, and connected only by a fine brass double-acting, ball-valve pump.

The chemicals, which are called No. 1 and No. 2, are carried in separate boxes, one on each side, a charge in each box. The tanks are filled with clear water, and in case of fire the chemicals are put in, one package in each tank. The pump is worked with one hand and the hose directed on the fire with the other, the pump drawing from one side water charged with No. 1 and from the other charged from No. 2, the two coming together in the chamber and hose, thus forming a powerful stream of water highly charged with carbonic acid gas, the great destroyer of fire.

This machine is very simple indeed, and is durable because there are no chemicals to corrode the material of its construction. There is never any pressure in the tanks, and there is therefore no danger of their bursting.

This machine can be tested at any time by simply taking a couple of strokes with the pump. Moreover the contents can be replenished in a moment when the charge is out; or water alone can be forced on to the embers when the chemical charge has been expended. There is no danger of a machine exploding on a man's back, as the chamber contains no gas, the gas forming where the streams are brought together in the top of the pump. The apparatus

is set on the ground, and the pump operated in that way, so that a very powerful stream can be sent.

A company has recently been formed to manufacture the apparatus. The machine is called the "Climax Fire Extinguisher," and has been patented.

For miners' use, particularly, this is a very efficient machine, as with it an incipient fire in a shaft or drift can be quickly and readily stopped. A few of the machines, set in the different parts of a mine and always ready for use, would be invaluable, and they are easily and readily operated and are very effective.

Some tests were recently made at the Mare Island navy yard by order of the Secretary of the Navy, and Commodore Phelps, Commandant, reports as follows:

"In compliance with your order of October 16, 1882, directing me to test and report upon the value of a 'fire extinguisher' invented by A. F. Spaw, I respectfully submit the following:

"A pile of light wood, tar barrels, etc., well sprinkled with refuse tar and pitch, about 8 feet in diameter and height, was lighted, and when well on fire the stream from the extinguisher was brought in play. Wherever it struck the fire was at once put out.

"On the 10th inst., another trial of the 'extinguisher' (similar in every respect to the first) was made, with the same result so far as it was concerned; and in competition with a new Martin's, recently charged for the purpose, and showing on its gauge a pressure of 102 pounds, against a separate fire of precisely the same character, it showed a decided superiority. The latter made no impression whatever, and when exhausted the fire was burning as fiercely as at the commencement.

"The principal advantages of Spaw's (not considering the nature of the chemical) are that it is charged only when needed for actual use; is in immediate readiness, and can be re-charged as often as required without interfering with its action; that the charges being kept dry, do not deteriorate any more than the spare ones furnished for the extinguishers (Martin's) now in use; and that the apparatus itself, not being under the continual heavy pressure of those now furnished, do not become useless through leaks."

"The number of real estate sales in San Francisco in 1881 was 2,277, amounting to \$12,233,933, while 2,835 sales, of the value of \$15,127,200, were made in 1882. The increase was, in value, mostly in the business portion of the city. Down-town business property of all kinds has increased in value within a year \$50,000,000. Many properties lying north of California street, which had been for sale for one to three years and could find no buyers, all went off in 1882, and generally at an advance on the old prices.

Overworked men and women, persons of sedentary habits, and others whose system needs recuperation, nerves toned and muscles strengthened, should use Brown's Iron Bitters.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 252, Market St., S. F.

FOR WEEK ENDING DECEMBER 26, 1882.

269,613.—LETTER AND BILL FILE.—Frank D. Adams, Auburn, Cal.
269,563.—ORE CONCENTRATOR.—W. P. Davis, Spring City, Nev.
269,556.—STEAM TRAP.—A. L. Fish, S. F.
269,588.—WATCH REGULATOR.—J. C. Landmann, Dutch Flat, Cal.
269,589.—DEVICE FOR BREAKING BALKY HORSES.—Jos. Lucas, Los Angeles, Cal.
269,701.—HEADER AND THRASHER.—Wm. H. Parrish, Salem, Or.
269,719.—DRAFTING INSTRUMENT.—H. C. Root, S. F.
269,610.—SEWING IMPLEMENT.—Maria A. Wilson, Grayson, Cal.
9,907.—TRADE MARK.—Granite Powder Co., S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

AT New York agents of the leading steamship lines complain that the shipping trade is in anything but a satisfactory condition. The British lines complain of the competition of the small and slow independent steamers known as ocean tramps.

THE officers of the Chicago Exposition propose that the city government allow them 4% dividends on their stock per annum and allow certain annual improvements, and that the balance of money earned be set aside for a public art museum.

PLAIN TRUTHS

The blood is the foundation of life, it circulates through every part of the body, and unless it is pure and rich, good health is impossible. If disease has entered the system the only sure and quick way to drive it out is to purify and enrich the blood.

These simple facts are well known, and the highest medical authorities agree that nothing but iron will restore the blood to its natural condition; and also that all the iron preparations hitherto made blacken the teeth, cause headache, and are otherwise injurious.

BROWN'S IRON BITTERS will thoroughly and quickly assimilate with the blood, purifying and strengthening it, and thus drive disease from any part of the system, and it will not blacken the teeth, cause headache or constipation, and is positively not injurious.

Saved his Child.

17 N. Eutaw St., Baltimore, Md.

Feb. 12, 1880.

Gents:—Upon the recommendation of a friend I tried BROWN'S IRON BITTERS as a tonic and restorative for my daughter, whom I was thoroughly convinced was wasting away with Consumption. Having lost three daughters by the terrible disease, under the care of eminent physicians, I was loth to believe that anything could arrest the progress of the disease, but to my great surprise, before my daughter had taken one bottle of BROWN'S IRON BITTERS, she began to mend and now is quite restored to former health. A fifth daughter began to show signs of Consumption, and when the physician was consulted he quickly said "Tonics were required," and when informed that the elder sister was taking BROWN'S IRON BITTERS, responded "that is a good tonic, take it."

ADORAM PHELPS.

BROWN'S IRON BITTERS effectually cures Dyspepsia, Indigestion and Weakness, and renders the greatest relief and benefit to persons suffering from such wasting diseases as Consumption, Kidney Complaints, etc.

Goods and the "GARLAND" IMPROVED SEWER GAS TRAP MFG CO., 1501 Broadway, Oakland, Cal.

THE "Garland" Patent SEWER GAS TRAP Is a sure shut-off against Sewer Gas and Back Water. The Loaded Metal Ball Valve is slightly heavier than water. This Trap can be put in at small expense, and is warranted to give satisfaction. Highly recommended by leading Architects and Plumbers. Used in all new, first-class buildings in San Francisco, including Phelan Block. For sale by all dealers in Plumbers' Goods. Sent by mail on receipt of \$2.50. Send for 125 page Illustrated Catalogue of 3000 Standard Goods on every subject. Agents wanted. National Book Company, 73 Beckman Street, New York

Mining and Other Companies.

Persons interested in incorporation will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

"THE \$1,000 CHALLENGE"

Ore Feeder for Quartz Mills.

OVER 800 ARE NOW IN USE, GIVING ENTIRE SATISFACTION.

Awarded First Premium at the Tenth and Twelfth Industrial Fairs of the Mechanics' Institute.

Twenty Per Cent. More Ore Crushed with Fifteen Per Cent. Less Wear of Iron than by and Feeding.

The accompanying cut illustrates the recently introduced Grip, and also the Spring Attachment, which replaces the Weight heretofore used, and which are obvious improvements.

It is now fully demonstrated, after careful and long continued experimentation and practical use, that the plan upon which a perfect Ore Feeder must be constructed is that of a carrier, and not that of a shaking-table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Jerky or spasmodic discharges will not answer the purpose for wet or sticky ores.

The Challenge Ore Feeders are now in use in the following Mills, besides many others:

Souley.....	20 Stamp.....	Tuolumne county, Cal.
Sheep Ranch.....	20 ".....	Calaveras " "
Mahoney.....	40 ".....	Amador " "

Hidden Treasure.....	40 ".....	" " " "

Superiority of the "Challenge" Ore Feeder Demonstrated!

At the "Christy" Mill, Utah County, Utah, the "Eclipse" Feeders, (concoiled by E. Coleman) were introduced, but not carrying a regular supply of ore for the crushing capacity of the stamps, were replaced by the "Challenge," which are now running and the stamps crushing forty (40) per cent. more ore than was done by the "Eclipse."

The "Harshaw" or "Hermosa" Mill, of Patagonia District, Arizona, was also originally fitted with "Eclipse" Feeders, but after a few weeks trial they were pronounced inadequate to the work, discarded, and the "Challenge" adopted.

The "Silver King" Mill of Arizona, also removed the "Eclipse" Feeders to give place to the "Challenge."

The "Sola" Mill, of Brown's Valley, Yuba County, Cal., was fitted with "Victor" Feeders, manufactured by E. T. Steen, but proving inefficient, the "Challenge" Feeders were substituted.

Four of the "Victor" Feeders, manufactured by E. T. Steen, were also placed in the "Alexander" Mill, at Grantsville, Nevada, but after a fair trial were discarded, and Hendy's Feeders fitted, and four others of the same pattern added when the second twenty stamps were erected.

These cases are simply cited from among many similar instances, in proof of the vast superiority of the "Challenge" Feeders over all others.

JOSHUA HENDY, Agent,

Machine Works 49 and 51 Fremont Street, San Francisco.

Manufacturer of Quartz, Saw Mill and General Machinery. Also Agent for BAKER ROTARY PRESSURE BLOWERS, and WILBRAHAM ROTARY PISTON PUMPS. P. BLAISDELL & CO.'S Machinists' Tools. HOT POLISHED SHAFTING from the Akron Iron Company, of Akron, Ohio.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS

All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

- NO. 1.—The most Powerful Explosive Compound now in use here.
NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much finer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same.

—FOR—

Galena Silver & Copper Ores.

The PACIFIC WATER JACKET SMELTERS embrace many features that are entirely new and of great practical utility, which are covered by letters patent.

No other furnaces can compare with these for durability and in capacity for uninterrupted work.

MORE THAN SIXTY of them are now running on the Pacific Coast, giving results never before obtained as regards continuous running, economy of fuel, grade and quality of bullion produced. We are prepared to demonstrate by facts the claims here made.

These Smelters are shipped in a complete state, requiring no brick or stone work, except that for the crucible, thus saving great expense and loss of time in construction.

Complete smelting plants made to order of any capacity and with all the improvements that experience has suggested as valuable in this class of machinery. Skilled and experienced smelters furnished when desired to examine mines and to superintend construction and running of furnaces. Estimates given upon application.

Send for circular.

MINING MACHINERY A SPECIALTY.

Our manufactures of min-
ing machinery embrace
every kind of machine and
appliance for the mining
and reduction of ores.
We have had an expe-
rience of more than twenty
years in the manufacture
and practical operation of
mining machinery in Colo-
rado and the neighboring
States and Territories.

Our facilities are superior
to those of any manufac-
turer in the West, our works
having been recently re-
built, greatly enlarged and
completely equipped.
We invite the investiga-
tion of mine owners and
mill men seeking machin-
ery. We can furnish, on
board, at our works, or set
up at the mines anywhere
in the Rocky Mountain re-
gion, on short notice, the

following machinery:
Cornish Pumps, Steam
Pumps, Stamp Mills for
Wet or Dry crushing, Fans,
Settlers, Agitators, Retorts,
Bullion and Ingot Moulds,
Reverberatory Furnaces,
Buckner Cylinders, Revolv-
ing Roasting Furnaces and
Dryers, Melting Furnaces,
Concentrating Machinery,
Rolls, Crushers, Conveyors
and Elevators, Ore Sam-
plers and Grinders, Hoist-
ing Engines, Water Jacket
Furnaces, Slag Pots and
Cars, Lead Pots and Ladles,
Blast Pipes and Water
Towers, Blowers, Cupel-
lating Furnaces, Market
Kettles, Wire Rope, Cages,
buckets, Slips, Ore Cars, etc.
Estimates furnished and
prices quoted on applica-
tion. Send for illustrated
catalogue.

MILL AND MINING MACHINERY.

F. A. HUNTINGTON,

No. 45 Fremont Street, - - San Francisco, Cal.

Oscillating Stamp Mill.

It has no Stems, Cam, or Tappets, and adjusts itself to the wear of the Shoes and Dies.
For simplicity, economy, durability and effective working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power. Awarded First Premium and Medal at Mechanics' Fair, S. F., 1880.

Manufactured by
F. A. HUNTINGTON, FRASER & CHALMERS,
45 Fremont St., S. F., Cal. | 145 Fulton St., Chicago, Ill.
Improved Patent Grinding and Amalgamating Pans, Concentrators and Gold Amalgamators. Also, Steam Engines and Mining Machinery of all kinds. Send for circulars.

F. A. HUNTINGTON,
45 Fremont Street, San Francisco, Cal.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

Send for Circulars.

SHINGLE MACHINE.

For simplicity, durability and rapidity of action, these Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

SAWMILL MACHINERY,

MINES WANTED.

Two Gold, one Copper and one Antimony, for CASH CUSTOMERS. Mines will be as good as sold if first-class and accompanied with favorable Reports from Experts of known reputation. No PROSPECTS wanted, and no mine without an Expert Report will be entertained. Apply in person or by letter to

A. M. LAWVER,

45 Merchant's Exchange San Francisco, Cal.

This paper is printed with Ink Manufactured by Charles Eneu Johnson & Co., 509 South 10th St., Philadelphia. Branch Offices—47 Rose St., New York, and 40 La Salle St., Chicago. Agent for the Pacific Coast—Joseph H. Dorety, 529 Commercial St., S. F.

SULPHURETS.

Clean Concentrations wanted. A party from the East having a process for working low-grade Sulphurets, will commence purchasing the same as soon as assured of an abundant supply. Gold-bearing Sulphurets preferred, having an assay value of \$20 per ton, or upwards. Address,

A. B. WATT, P. O. Box, 2293, San Francisco.

VOLUME XLVI
Number 2

Miners' Association of California.

The State Miners' Association is again calling upon the miners of California to contribute to the fund to enable the Association to meet the expenses of the continued litigation against the hydraulic miners by the anti-debris men. It will be remembered that this Association when first formed was composed only of hydraulic miners; but now quartz miners are also enrolled. The Association is sending circulars to miners in all parts of the State, asking for aid. The circular is as follows:

OFFICE MINERS' ASSOCIATION,
320 Sansome St., Room 23,
San Francisco, Jan. 1, 1883.

DEAR SIR:—Your locality will soon be visited by an accredited agent of this Association, who will on its behalf solicit contributions to the "defense fund" of the Miners' Association.

We call the attention of your citizens to the magnitude of the litigation pending in the United States and State courts. All the prominent companies have been sued and many are enjoined.

Our opponents aim at nothing less than the suspension of the mining industry. It is a mere question of time when service will be made on all class of mines.

To that end, our opponents are collecting a large fund for the employment of lawyers, engineers and witnesses, and are organizing their forces with a further view to legislation hostile to the miners in the Legislature of 1883.

Not content with appropriations of \$1,000 from their respective city and county treasuries, they have appealed to all classes for pecuniary aid. The land owner contributes according to his means, represented by taxable value of his property. The laborer is called upon to pay his contribution, and the women and children have been solicited to donate their savings. Their organizations extend from the mouth of the Sacramento to its head, and from the Coast Range to the Sierra Nevada. No person can refuse to contribute under the penalty of social ostracism.

And yet how insignificant their injuries, either proven, alleged or threatened, to the great calamity which would befall the mining counties, if they should prevail in their endeavor to crush the business of mining! In a few years the mountain counties would present a scene of depopulated towns, empty school-houses and decayed churches. The fairest portion of our State would present an appearance more sad than that of provinces ravaged by war, famine and pestilence.

The burden of the defense of this great industry has fallen on a few companies, handed together under the name of the Miners' Association, and controlled by the advice of the leading miners of the State. Owing to the closing of some mines by injunction and the suspension of work in others, through the prevailing system of terrorism, and the expense of building dams, voluntarily incurred, the resources of the companies comprising the Association have been crippled, and we are compelled to adopt the tactics of our opponents and ask contributions from all classes of persons—for all are interested in the protection of their homes.

With a view to promote this object we ask you to give us your personal influence, and suggest that in each town and camp a subscription list be opened at the place of business of our local agents, where contributions may be received and retained until the arrival of our special agent, or be remitted to the main office in San Francisco. In either event, official receipts will be issued to the donors.

The name and standing of the Board of Council directing the policy of the Association, and its record in the defense of the mining industry, whenever and wherever attacked, is a guarantee that the mining interest will be protected in the future as in the past.

HAMILTON SMITH, JR.,
President.

W. A. SKIDMORE, Secretary.

DURING the past year five Michigan mining companies paid their stockholders \$340,000 more than the actual paid-up capital of the companies.

The Tariff and Mining.

The miners of the country are as much interested in the questions connected with the tariff as any class of the community. In fact, they are very much more interested than most persons. The imposition or removal of a duty means often to them profit or loss, a continuance or stoppage of business. Just at the time when the tariff is being considered by Congress

timony, 10% *ad valorem*: borax, 10 cents per pound, while its value in the market is only 10 cents per pound; copper, 3 cent per pound; tin, 15% *ad valorem*; steel, 30% *ad valorem*; copper ore, 3 cents per pound; copper, in plate and bars, 5 cents a pound; nickel, 30 cents a pound; brass, 15% *ad valorem*. Manufacturers of brass, iron, lead, pewter, tin, etc., not otherwise provided for, pay 35% *ad valorem*, under which clause the quicksilver miners must pay 35% duty on iron flasks. Gunpowder used for

BLAKE'S SINKING PUMP FOR MINES.

and a revision is being made, the miners are uneasy. The quicksilver and lead miners particularly are watching carefully what is being done. We give in other columns of this number of the PRESS full statements of the case of both these interests. The lead miners protest against a reduction of the tariff, claiming that it would ruin the business of lead mining by making it unprofitable. The quicksilver miners ask to have a duty imposed on that metal, as was formerly the case, the absence of any duty working a hardship to their industry, and having caused the closing down of many mines in California.

California is not so much interested in the lead as in the quicksilver, as she is sole producer of the latter in this country, while of the former she produces very little. Quicksilver was put on the free list by Act of February 8, 1875. Under the present tariff the following minerals and ores are protected by duty: An-

timony has a duty of 6 cents a pound, or 20% *ad valorem*.

The mining community should give close attention to these tariff questions, and should act together to protect their interests. A passive grumble at proposed adverse legislation is of no use, but active measure must be taken. The quicksilver and lead miners have both presented their ideas of the question to Congress in the form of memorial and protest, and by united action hope to gain their points.

MADE INSANE BY NOXIOUS GASES.—At the Albion works, Enreka, McDonald, a smelter, who had been in one of the tunnel fume escapees to make some repairs, was overpowered and rendered unconscious by noxious gases. When resuscitated McDonald was for a time violently insane. He seized a sledge hammer and charged upon his friends. Being overpowered and sent to bed he came out all right in a few hours.

State Mining Bureau.

Governor Perkins, in his message to the Legislature, has the following to say commendatory of the State Mining Bureau:

I commend the report of the State Mineralogist to your careful consideration. It is one of the most important documents submitted for your investigation. At a comparatively small cost, it contains more practical information relative to the mineral wealth of the State than will be found in the reports of the State Geological Survey, at an enormous outlay. The appointment of Professor Henry G. Hanks as State Mineralogist was a fortunate selection, and I take pleasure in thus publicly acknowledging his services, eminently deserved by his unceasing exertion and devotion in advancing the interests and influence of the Bureau. Its usefulness has been recognized by the leading scientific institutions of Europe and America, attested by a voluminous correspondence on file in his office.

The catalogue of its collection of minerals, metals, and other articles, bears testimony to the labor required, and which must have been expended, not only in procuring, but in placing them in classes appreciable to the visitor; and I would here suggest the propriety of transferring the mineral collection now in the State Library to the Bureau. It will be seen by the financial exhibit that it will be impossible to continue the Bureau unless an appropriation is made for its future support. The State should pay from the General Fund the salaries of the Mineralogist, Secretary, Chemist and Janitor, and the rent and the insurance of the building; and permit the money raised by the provisions of the Act to be used for the benefit of the Museum proper, the traveling expenses of the State Mineralogist, incidental expenses, and such extra help as I am satisfied is at times required. To remove the burden and responsibility which so important a trust devolves on one person, I would recommend the Act creating the Bureau be amended by placing its management under the charge of a Board of Trustees, who, in connection with the State Mineralogist, shall have the control and supervision of the same. This is also the desire of Mr. Hanks, as expressed in his report.

The Blake Sinking Pump.

The engraving on this page represents Blake's Improved Sinking Pump of the vertical double-acting plunger pattern for mining operations, sinking well-shafts, etc. For sinking new shafts, recovering old mines that have been "drowned out," and for mining operations requiring the use of a light, portable and efficient steam pump, or for sinking wells and general excavation work, this improved sinking pump is especially adapted.

The pump being vertical requires but little room in the shaft. It will throw a steady continuous stream of water, and will work equally well when hanging by the tackle or when hooked to the timbering. Ten sizes of this style of pump are made, with capacities from 33 gallons a minute up to 400 gallons, and from 7 to 18 inches stroke. Estimates will be furnished also by the agents for larger sizes when required.

The pump is arranged with a strong bolt, as shown, firmly imbedded in the upper steam cylinder head, to which tackle for raising or lowering can be readily attached. Adjustable wrought iron dogs for hanging the pump to the shaft timbering are bolted to the cylinders. The lower plunger works on a removable cylinder of gun-metal composition, which can be readily replaced with but little trouble and expense by a new one when worn out. The water valves are of the best vulcanized rubber and work on seats of gun-metal composition. Swing bolts admit of easy access to the crater-valve and pump-barrel. The details of operation of the Blake mining pumps are well known to mining men, and this one differs only in form, the valve, etc., being all on the same general principle. H. P. Gregory & Co., mining machinery and supplies, 2 and 4 California street, in this city, are general agents for the Blake pumps.

California State Geological Society.

President's Annual Address.

In the last number of the PRESS we gave the result of the annual election of this society, and promised to give this week the annual address of President Hanks, which was as follows:

On retiring from the office of President, with which you have honored me, it will be fitting to give you a history of the Society since its commencement, and some account of its doings, what it has accomplished, and what may be hoped for in the future.

The California State Geological Society was organized for the purpose of making a State geological collection, while the facilities for doing so were better than they would be in the future, owing to unusual activity in prospecting, caused by the discovery and development of rich mines of gold and silver in California and Nevada.

The first meeting of the Society was held Dec. 22, 1876, and the incorporation papers filed Dec. 30, 1876. As it was thought upon due deliberation that a limited number of active workers could secure that end sooner than a cumbersome organization, the number was limited to 10.

It was thought by the projectors that at least 10 years might elapse before a collection could be made worthy of the acceptance of this State. Unexpected success attended the efforts of the *decemviri*, and the acquisitions soon became valuable and extensive, growing quite beyond the expectation of the society.

The Society and the Mining Bureau.

In 1880 the Hon. Joseph Wason, a member of the Legislature, became interested in the society's doings, and proposed to introduce a bill to establish a Mining Bureau and State Museum. The matter was brought before the society, by whom it was thought too early to make the attempt. Mr. Wason, however, differed in opinion; the bill was introduced, meeting with success, and the institution was created, the Mining Bureau bill being approved April 16, 1880.

The main object of the society being thus unexpectedly accomplished, meetings were for a time discontinued, but the interest of the members did not wane. At a meeting held May 29, 1880, the collections, consisting of 1,327 geological specimens and 103 books and pamphlets, were presented to the State by the following resolution:

On motion, duly seconded, it was

Resolved, That the entire collection of minerals of this society, its books, and all of its property, except its desk, record book and seal, be, and the same are, hereby donated to the State of California, subject to the conditions set forth in the by-laws of the society. The President and Secretary are hereby authorized to make the necessary conveyance, and the Secretary is directed to deliver all of said property to the State Mineralogist, to be by him held in trust for the State of California.

On motion, duly seconded, it was

Resolved, That the specimens and books hereafter received by the society be given as fast as received to the State Mineralogist for the State Mining Bureau.

It was understood that in due time the meetings would be resumed, and the society, having no property, nor desiring any, would become a purely scientific one, and would direct its energies toward building up the State Museum and Mining Bureau.

The reasons for a limited membership having ceased to exist, it was decided to modify the by-laws to admit of increase to any extent. With this view, at a meeting held September 21, 1882, a committee was appointed to revise the by-laws, consisting of Messrs. W. S. Keyes and S. Heydenfeldt, Jr., who reported at the next meeting the revised by-laws, which were accepted.

The change of laws abolishes all classes and permits unlimited membership.

It was decided that this, the sixth anniversary, should be the era for the new dispensation, and I trust that the California State Geological Society will now, as proposed, take a new start and assert itself.

The proceedings of the Society have been quietly conducted, but, while it has accomplished more than was expected, or even hoped for by its founders, it has been too modest and too retiring in its character. While its membership in California has been small, its numbers among its associates abroad some of the most noted men of science.

Since its organization the Society has lost seven members by death. Of the original ten, Joseph Roberts, Jr., and Thomas J. Owens have died. Of associate life members, four have been taken from us, Louis V. B. Howell, Frederick MacCrellich, Seth Robinson and John D. Barry. Of corresponding members Charles Darwin is the only one of whose death we have received notice.

The State Geological Society greatly assisted the Paris Exposition Committee in their efforts to have the mineral resources of the State and the Pacific coast represented at the World's Exposition of 1878, which became a success on receiving material aid from the generous John W. Mackay.

State Museum.

It has been the desire of California Legislatures in years past to provide for a State Museum, but circumstances have interfered with its accomplishment.

In 1878 the Act of the Legislature creating

the State Geological Survey provided in Section 1 for a State Museum in the following words:

J. D. Whitney is appointed State Geologist, whose duty it shall be, with the aid of such assistants as he may appoint, to make accurate and complete geological survey of the State, and to furnish in his report of the same proper maps and diagrams thereof, with a full and scientific description of its rocks, fossils, soils and minerals, and of its botanical and zoological productions, together with specimens of the same, which specimens shall be properly labeled and arranged, and deposited in each place as shall be hereafter provided for that purpose by the Legislature.

In the preface of "Geology," Vol. I, folio 24, Prof. Whitney states that a large collection has accumulated, but that no provision had been made by this Legislature for a museum. Owing to this oversight, the fine collection made by the Geological Survey was destroyed by fire when stored in a warehouse supposed to be fire-proof, and, like the destruction of the Alexandrian Museum, on a lesser scale, a vast amount of valuable material was lost to the State, to the world and to science.

The same danger menaces the well advanced and very valuable museum of the State Mining Bureau and the inestimable collections of the California Academy of Sciences.

The Legislature of 1862-3 passed a joint resolution appointing a committee, consisting of Prof. J. D. Whitney, John Swett and J. F. Houghton, to report to the Legislature upon the feasibility of establishing a State University, an Agricultural College, a School of Mines and a Museum.

Prof. Whitney, in a lecture before the Mechanics' Institute held at Platt's Hall, Jan. 28, 1864, calling attention to the importance of a State Museum, said: "The interests of the State demand that these collections should be placed in a fire-proof building, which may be called the State Museum, where they will be accessible for the purpose of instruction, not only to the student, but to the general public."

Through the instrumentality of the State Geological Society and Acts of recent Legislatures, the foundation of the desired State Museum is already laid. As may be seen by an inspection of the cases of the Mining Bureau and the nucleus library of the same, the institution is not to be despised.

I congratulate you on the results of your efforts, to which are mainly due the accomplishment of this object.

When an institution in the interest of the general public is once established, it grows rapidly, for the reason that it is the inevitable destiny of private collections made by students, amateurs and specialists, to centralize, to gravitate to and become absorbed in great museums. No matter what they may think or do during their short lives, this will be the certain and final disposition of their collections. And this is right, for in no other way could the world be so benefited. Collectors hoard with a miser's acquisitiveness their small local collections, and gather together what will be of inestimable value in a scientific and practical sense, to those who follow, and while future generations will not thank them individually, they will not and cannot ignore the obligation. This is the experience made in all countries where museums have grown up, and the great collections in the world's centers are aggregations of small ones made principally by individuals. The same will be the case on the Pacific coast. There is no city in the world where a complete Geological Museum is more needed, or will be more appreciated than in San Francisco.

Scientific Men of the Pacific Coast.

I feel it my duty to say something on this occasion in favor of the scientific men of California and the Pacific coast, for they do not always receive the credit they deserve. This class must include not only those who have attained eminence, but students with a bent toward scientific studies, who are equally deserving of respect and consideration. The prospectors also, as a class, must be included, for their pursuits create in them a desire to investigate the laws of nature, the results of which they see on every side as they scour the hills and valleys in search of mineral veins and deposits. As a class they would be scientific men if their most earnest desire could be accomplished. The want of education in some cases and adverse circumstances in others have defeated their aspirations. They are, as it were, rough diamonds, deficient merely in the polish that can only be imparted by education. It can be shown that this State and the world have been benefited by the labors of these men to a much greater extent than can ever be repaid, and it is only justice to them to put in a claim for educational facilities to fit them for the better accomplishment of their labors.

There is a class of scientific workers whose happiness depends on the pursuit of knowledge. They may be found in almost every part of the State and in every social condition. In the large cities they institute societies in which they toil for years in poverty, to be at times ridiculed, and but seldom encouraged or appreciated. They may be found in the mountains in rough dress, with mining tools on their shoulders, climbing hills while looking for mines of silver, gold, lead, copper and other metals, or searching the deserts for deposits of salt, borax and soda. It is through the efforts of this class of men that the glorious State of California is 100 years in advance of the frontier Territory

it would have been had the land been suited only for agricultural purposes. They were the pioneers who paved the way for the railroad made known the physical features of the country, and made it possible for us to rear our families in safety on lands which but a few short years ago were the range of the savage and of wild animals. While they believed they were working for themselves they were in reality the agents of a providence which has given to the world a California and a Pacific coast.

Scientific men generally become so without any premeditated plan; on the other hand, attempts to make them to order generally result in failure. Scientific men, and especially those who become noted as such, are too frequently jealous of each other. But I will not say that these very jealousies are not productive of good, and the world benefited by the rivalry thereby engendered. They should more generally join forces and work in harmony, give their ideas and the results of their original researches to the world for the benefit of mankind during their lives, rather than (by the posthumous publication of their works) be referred to after death as noted men of science.

"A prophet is not without honor save in his own country"—so a scientific man is seldom appreciated during his life. History is filled with such examples. They are generally poor and their pursuits tend to a continuance of that condition, and as they seldom become wealthy by the practical application of the discoveries they make, they should at least be indulged in their peculiarities and thanked by those who gain riches, health and convenience from their labors.

Mining Schools.

To aid prospectors in their labors and studies there should be some institution, fostered by the State, where men wishing to spend a few days, or weeks, in learning to distinguish minerals or to assay ores, could be able to do so without expense and without preparatory study, by simply making application and expressing the desire.

There should be a grand library of practical and scientific books, special works of reference, to which all should have free access during suitable hours daily, with conveniences for making memoranda. These books, being of a reference character, and unlike those in public libraries, should never be permitted to leave the rooms, and should be carefully watched to prevent mutilation and theft.

California is one of the largest States in the Union, having an area of nearly 189,000 square miles. A corresponding sea coast on the Atlantic side of the continent would extend nearly from Boston to Savannah. With such a vast scope of only partially explored territory at your feet, you will have ample opportunity to employ your leisure in collecting geological facts and leave something to be done by future generations. Scientific men in older countries envy us the new field open to our investigations, and look to us for original work.

I trust the California Geological Society will not only do all in its power to collect information relating to this almost virgin field, but also publish its proceedings for the benefit of the world.

The Tariff on Lead.

Vigorous Protest Against a Reduction.

The American Association of Mining Industries has issued the following "Protest A," which is being circulated in Colorado for signature:

To the Honorable the Senate and House of Representatives of the United States:—As miners and men of business, desiring to see our country prosperous and progressive commercially, socially, and in all other advantageous directions, and recognizing the indubitable fact that the trades and industries which, when flourishing and self-sustaining, lead to this worthy end, and that these trades and industries depend largely upon each other for their aggregate success, we earnestly and anxiously protest against any movement for reductions in the tariff on lead and copper and their ores.

The mining and reduction of base ores, especially those of lead and copper, form one of the strongest interests in the State; an interest in which much of the present prosperity of the State, and that which is anticipated, lies, and we desire to present to your honorable bodies that the contemplated reduction of tariff upon the ores and metals named would utterly ruin and shut off this industry, for only under the protection of the tariff can it be possible to conduct the work of mining and reducing lead and copper with that success which would lead to any extensive operation therein.

The greatest commentators upon tariff questions, and even those who have most strenuously advocated free trade, have agreed that it is most expedient to give tariff protection to certain industries in new countries, provided the country under consideration has good natural resources for the prosecution of the industry thus to be protected.

Without intent or desire to discuss tariff matters, further than to present our just claim in the single proposition in hand, we beg leave to offer that ours is certainly a new country, and that there can be no manner of doubt as to its natural resources in the direction suggested, or that the industry and interests involved have most prospered under tariff protection against foreign competition.

To abolish this protection against foreign lead

and copper is to paralyze not only the direct industries which mining and reducing them fosters in this State, but it would seriously injure many and other important industries that are largely dependent upon the first named to wit: the manufacturing industries which manipulate lead and copper, and which give employment to thousands; the merchants and farmers who supply the miners and artificers of these metals with the necessities and comforts of life in the way of food, clothing, etc.; the railroads and other common carriers, and other various branches too numerous to specify, in trade and commerce, which the interests mentioned permeate and ramify.

It is this multiplying and diversifying of the departments of home industry, bringing the farmer, the mechanic, the merchant, the manufacturer, the miner, and the common carrier, into immediate contact and community of interest, enabling them to interchange their products, necessities, and accommodations, which makes any country, and especially a new one, successful and prosperous.

The high price of coals and other material, the use in mines of large quantities of steel and iron, the heavy machinery required that must be taken into them to work them, incur not only great cost in purchase, but a vast expense in freight, and it is certain, therefore, that but for the protection afforded by the tariff on lead and copper, so largely produced in this State, not a pound of either would have been produced, and for the same reason a reduction of the tariff would operate to hinder and shut off the production. The tariff is, in short, the very life of the industries mentioned and those correlative.

That the prosperity of the whole country is the first thought and aim and care of your honorable bodies, we entertain no doubt, and we submit that in order to foster the industries of the whole country as an aggregate, those of sections should be encouraged, sustained, abetted and upheld in detail. In Colorado all branches of business are made more valuable and prosperous by the protection of her mines, which enables her people to work them and render them productive and valuable to the State and the world.

The lead and copper interests of Colorado, though yet in their infancy, are capable of prolific production of wealth, and will be extensively advanced by the prosecution of operations in the present mines, the opening of new ones, and the erection of numerous additional works for the reduction of ore, if your honorable bodies heed our petitions and memorials, and thus insure the protection desired, which is, beyond peradventure, a *sine qua non* in the premises.

The Leadville Protest.

The miners and smelters of Leadville, Colorado, have signed a protest addressed to the Committee on Finance of the Senate, and to the Committee on Ways and Means of the House of Representatives, and filed with the said committees on December 23, 1882. The protest is as follows:

The undersigned, who are well acquainted with the lead industry of Leadville, Colorado, and of this country, respectfully submit the following facts for the consideration of your honorable body.

Until the tariff on lead ores was threatened with a reduction the price of lead was \$100 a ton. At that rate the Leadville smelter can pay \$40 a ton for the lead in the ore. The remaining \$60 is consumed in loss in treating, freight, rebating, commissions, etc. With the present tariff of two cents per pound on lead, equivalent to \$40 a ton, lead cannot be imported at a profit; with the tariff reduced to one and one-half cents per pound, equivalent to \$30 a ton, lead could be imported and sold at a profit with a slight advance on \$90 a ton. At \$90 a ton the Leadville smelter could only pay \$30 a ton for lead.

Product of Colorado.

Leadville and its adjoining and tributary camps (Red Cliff, Kokomo and others) now produce about 1,000 tons of ore per day, or at the rate of 300,000 tons per annum; 100,000 tons of this ore now net the mine owner not to exceed \$2 a ton. This ore averages from 25 to 30% lead, for which the smelter now pays at the rate of 40 cents per unit, but for which he could only pay at the rate of 30 cents per unit, with lead at \$90 a ton, i. e., the mine owner would receive 10 cents a unit, or from \$2.50 to \$3.00 a ton less for his ore, which exceeds his present profit.

Of these 100,000 tons not to exceed 10,000 tons are mined in mining the richer ores, so that the remaining 90,000 tons would not be mined at all in the case of a reduction of the tariff. These 90,000 tons would cost an average of \$12 a ton to mine, equal to \$1,050,000, and \$12 a ton to reduce, equal to \$1,050,000 more, or a total of \$2,100,000, the whole of which sum is now expended in this camp as follows: Labor, \$1,500,000; supplies, \$650,000. As it costs no more to mine and reduce the higher grades of ore than the lower, the reduction of the tariff by one-half cent per pound on lead would reduce the demand for labor and supplies in this camp to two-thirds of the present. In addition to this loss to labor and supplies, the mine owner and the smelter together would lose a profit of about \$360,000 on the 90,000 tons of ore that could not be mined with the reduced tariff, and the mine owner would in addition thereto lose about \$320,000 on the lead produced from the

(CONTINUED ON PAGE 23).

MECHANICAL PROGRESS.

What Dr. Seimens Expects From the Gas Engine.

In his 1883 inaugural as President of the British Association, Dr. Seimens suggested that the time might not be far distant when the gas engine would displace on board our ships the somewhat complicated and dangerous steam boiler now in use. The advent of such an engine and the dynamo machine he declared must mark a new era of material progress, at least equal to that produced by the introduction of steam power in the early part of the century.

The great advantage of the gas engine is believed to be in its saving of fuel. According to Dr. Seimens the best steam engine yet constructed does not yield in mechanical effect more than one-seventh part of the heat energy residing in the fuel consumed, when as the factor of efficiency of the gas engine is one quarter. If, therefore, it shall be adapted to vessels, the gas engine, being of half the weight of the present steam engine and boilers, and working with only about half the present expenditure of fuel, will admit of an addition of 30 to the cargo of an "an Atlantic propeller vessel—no longer to be called a steamer." That improvement accomplished, the balance of advantages in favor of such vessels would be sufficient, as he says, to restrict the use of sailing craft chiefly to the regatta of sportsmen.

As it is now, steam is rapidly driving sails from the ocean, just as iron and steel are superseding wood for ship construction. Out of the 780 vessels building, or preparing to be built, in the United Kingdom on the 30th of June last, only 130 were sailing craft, while 650 were steamships; and of this whole number only 49 sailing vessels and 6 steam vessels were of wood, while steel, or homogeneous iron, which is destined to become the great material for ship building, was used for 89 steam and 11 sailing vessels.

The great advances hitherto made in steam vessels have been in the direction of saving fuel in lighter machinery, in the substitution of the screw for side wheels, and in the use of iron and steel instead of wood for their construction. A wooden ship could not be built to perform like the *Alaska* or the *Arizona*. Whereas in the days of the old Colline line the steam was expended only twice, and the pressure carried was only 15 lbs.; the expansion now is 10 or 12 times and the pressure is 90 to 100 lbs. The old *Canardere*, the *Asia*, *Africa*, and *Canada* carried a pressure of only 10 lbs.

The consequence has been the enormous increase in the size of the ocean steamers and the great advance in their speed. In April, 1883, the *Sirius* first crossed the Atlantic in 17 days from Liverpool and 15 days from Queenstown. She was of 700 tons and 320-horse power. The *Servia*, built in 1881, has an extreme length of 530 ft., and a displacement of 13,000 tons. The *City of Rome*, built in the same year, is 600 ft. long, and has a displacement of 13,500 tons. The *Alaska*, which is 500 ft. long, and of 12,000 displacement, has done the distance between Queenstown and New York in 7 days, 4 hours and 32 minutes, and the return voyage in 6 days and 22 hours, a mean ocean speed of about 17 knots an hour, or more than double that of the first steam vessel which crossed the Atlantic.

Undoubtedly, if the gas engine shall be able to do what Dr. Seimens anticipates, it will give ocean navigation another and a strong impulse. Its far greater lightness, as compared with the steam engine and boilers, and its smaller consumption of coal to produce the same effect, will admit of a much larger cargo, and greater speed may be obtained without too much sacrifice of the cargo capacity of the vessel.

Length of Rails for Railways.

A new question among railroad men has recently sprung up regarding the most profitable and economical length for rails in the track. Up to 10 years ago, a rail 16 ft. in length was in general use; then the more prominent lines began laying a 32-foot length rail. Now several roads are introducing a rail 60 ft. in length, and as soon as the new mill in Chicago is fairly in operation, rails 120 ft. in length are to be manufactured and tested on one of the north-western lines. This mill will be the only one in the country to construct that a 120-foot rail can be turned out. The argument in favor of long rails is the fact that the chief wear on the rails is at the joints, which become battered usually long before the body of the rail is much worn. Then it is further argued that the wheels under the cars will wear a third longer on a 120-foot rail, they being more worn in pounding the ends of the rails than in the actual turning of the wheel. It will be noticed further that with the lengthening of the rail a heavier rail is taking the place of a lighter one, but few first-class roads now laying a rail lighter than 60 pounds to the yard. They claim that with a rail 120 feet in length, Champions of the long rails favor a rail that will weigh 70 or 80 pounds to the yard, weighing 80 pounds to the yard, a track will last a quarter of a century, with slight repairs in the way of new cross-ties. One objection will be, however, its great weight, which will make it difficult to handle, unless it be done by a derrick car.—*Mechanical News*.

A Helping Hand.

The boys who succeed in life are generally those who are always ready to lend a helping hand. The same is true with workmen generally, wherever they may be. During the progress of the boilermakers' strike in New York, a steamship needed some repairs on her boilers before she could sail. Nothing would induce the strikers to undertake the work. In the emergency the chief engineer appealed to his crew to help him out of the difficulty. This the latter cheerfully consented to do, and set to work with a will, finishing the job in time for the regular trip. The proprietors of the works where the repairs were made recognized the service by paying full time to the crew, and it is probable that these men will never have occasion to regret their action in this instance. They were not, however, obliged to do it. It was not the duty for which they were paid, and had they possessed the spirit of some workers they would have declined to touch the job. Many men, especially young men, have the idea that the performance of any service outside of the prescribed routine is a blow at their independence. John, who is engaged on the hooks, grumbles because his employer asks him to close the store in the absence of the porter.

The men who succeed, however, are they who are occasionally willing to sink dignity in the interest they feel in the business in which they are engaged, and who are not sticklers for an over-strict construction of the terms of their contract. The painter who drops his brush at the stroke of 12, and will not finish a piece of work which will take two minutes more to bring to completion, is not the one to become a master-workman. Oftentimes the employer is to blame for the lack of interest among his help and their disposition to demand the exact "pound of flesh." He is unsympathetic, "locks" them for a slight and unavoidable loss of time, and so engenders inharmonious or unfriendly relations. Where there is a mutual good feeling, each party to the contract will be alert to help the other in time of need.

Waste of Power in Friction.

The frequent use of the indicator for determining the amount of power consumed in driving shafting is of great value. From 30 to 50% of the power of engines is ordinarily used for this purpose. The running condition of shafts and bearings, the alignment, the quality of the lubricant, and the tension of the belt, all have an important effect on the amount of power need up in friction. These are every one liable to change.

The difference in the friction of a line of shafting in perfect order, and the same not in perfect order may not be such to attract attention by any outward sign. But the indicator will show a difference, and it is liable to be of considerable amount. The repeated employment of the indicator for this purpose is a simple and certain means for showing changes that may occur, and furnishes a reliable indication as to when this important consumer of power needs attention.

The friction of the shafting and loose pulleys located in a certain new building was found by indicator test to consume 19.34-horse power. At the expiration of 15 months a similar test of the same shafting showed a consumption of 26.64-horse power, being an increase of 35%. As far as those having charge were aware, the bearings and all the conditions were practically the same as before. A test on another engine showed an increase in friction amounting to 44% after the expiration of five months.

The use of the indicator, the determination of the actual performance by tests of boilers and engines, the careful examination of the uses to which steam is applied, not only detect the first source of waste, but locate the place of the second, and point to remedies for both.

EDGE TOOLS.—All cutting and piercing edge tools operate on the principle of the wedge. A brad-awl furnishes an example which all can readily understand. The cutting edge of the awl severs the fibers of wood as the instrument enters, and the particles are compressed into a smaller compass, in the same manner as when a piece of wood is severed by a wedge. A chisel is a wedge in one sense, and an ax, drawing-knife or jack-knife is also a wedge. When a keen-edged razor is made to clip a hair or to remove a man's beard it operates on the principle of the wedge. Every intelligent mechanic understands that when a wedge is dressed out smoothly it may be driven in with much less force than if its surface were left jagged and rough. The same idea holds good with respect to edge tools. If the cutting edge be ground and whet to as fine an edge as may be practicable with a fine gritted whet stone, and if the surface back of the cutting edge be ground smooth and true, and polished neatly, so that one can discern the color of his eye by means of the polished surface, the tool will enter whatever it is to cut by the application of much less force than if the surface were left as rough as they usually are when the tool leaves the grindstone. All edge tools, such as axes, chisels and planes, that are operated with a crushing instead of a drawing stroke, should be polished neatly clear to the cutting edge, to facilitate their entrance into the substance to be cut.—*Manufacturer and Builder*.

SCIENTIFIC PROGRESS.

SUNBEAMS.—The greatest of physical paradoxes is the sunbeam. It is the most potent and versatile force we have, and yet it behaves itself like the gentlest and most accommodating. Nothing can fall more softly and more silently upon the earth than the rays of our great luminary—not even the feathery flakes of snow which thread their way through the atmosphere as if they were too limy to yield to the demands of gravity like grosser things. The most delicate slip of gold leaf, exposed as a target to the sun's shafts, is not stirred to the extent of a hair, though an infant's faintest breath would set it into tremulous motion. The tenderness of human organs—the apple of the eye—though pierced and buffeted each day by thousands of sunbeams, suffers no pain during the process, but rejoices in their sweetness, and blesses the useful light. Yet a few of those rays, insinuating themselves into a mass of iron, like the Britannia tubular bridge, will compel the closely-knit particles to separate, and will move the whole enormous fabric with as much ease as a giant would stir a straw. The play of those beams upon our sheets of water lifts up layer after layer into the atmosphere, and hoists whole rivers from their beds, only to drop them again in snow upon the hills, or in fattening showers upon the plants. Let but the air drink in a little more sunshine at one place than another, and out of it springs the tempest or the hurricane, which desolates a whole region in its lunatic wrath. The marvel is, that a power which is capable of assuming such a diversity of forms, and of producing such stupendous results, should come to us in so gentle, so peaceful and so unpretentious a guise.—*Manufacturer and Builder*.

CURIOUS FACT CONCERNING BOILING WATER.—At a recent Association meeting, Mr. A. J. Haddock, A. I. C., related the following: A kettle filled with boiling water was hung in the hottest room of some Turkish baths, with the lid on. The temperature of the surrounding air was 262° Fahr. After about an hour the temperature of the water was taken, and indicated, as was expected, 212°. The kettle was then rehung with the lid off. The temperature of the room was now 252°. In 20 minutes the temperature of the water had fallen to 185°; in 30 minutes, to 178°; in 45 minutes, to 170°, and was evidently still falling. The manager stated that it generally fell finally to about 140°, when a point of equilibrium seemed to be established, and the water neither got hotter nor cooler. Mr. Haddock supposes this loss of heat was due to rapid vaporization and conversion of the sensible heat of the water into the latent heat of steam, and as dry air is a very bad conductor of heat (one of the worst known), the heat required to convert a portion of the water into steam had to be abstracted from the remainder of the water, thus lowering the temperature. In substantiation of this explanation, we know as a fact that if water is placed in a vessel over a large hunk of strong sulphuric acid, in the receiver of an air pump, and the air is exhausted, the rapid evaporation of one portion of the water will actually cause the rest to freeze.

PURIFICATION OF SULPHURIC ACID BY CRYSTALLIZATION.—In the *Zeitschrift für Analytische Chemie*, Tjeden Moddermann remarks that he has for some time been accustomed to prepare pure sulphuric acid by recrystallization of the hydrate ($\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$), and finds this seldom adopted method of purification to be really an excellent one. The author has experimented in this way upon acid containing considerable quantities of lead and arsenious and nitric acids, etc., and hypocrystallized recrystallization has in all cases obtained a pure acid from them. The method is very simple. The acid is mixed with sufficient water, and, in bottles two-thirds full, exposed to the cold in the open air on a frosty night. If the mixture has been properly made it is generally frozen throughout the next morning. The chief thing then is to carefully separate the crystals from the mother liquor, and for this purpose the author employs a centrifugal apparatus, so constructed that the acid only comes in contact with glass. The separation is very easily effected, and except in cases where an acid is strongly contaminated with the different oxides of nitrogen, one recrystallization is generally sufficient.

SEEING AND SIGNALING.—M. Carpentier tells us that the time elapsing between a person seeing a signal and being able to repeat it with his forefinger is about 13-100 of a second. With some people the interval is twice as long, but the above may be taken as the average. M. Carpentier terms the interval in question the "duration of luminous perception," and he measures it in a very ingenious manner. A black disk is set revolving at a given speed, and the observer faces it, having under his finger an electric key. There is a small opening or window in one part of the disk, and when this comes round opposite the observer he sees a light shining through it. Immediately he presses the key and an electric signal passes to the revolving disk. The disk is stopped, and the distance between the window and the record of the signal being measured furnishes the result. The distance between the two points on the disk is, of course, easily turned into time, since the disk was revolving at a known speed.

SCIENTIFIC SUGGESTIONS.—Prof. Lockyer is of the opinion that there are many facts suggested by the spectra of solar and stellar physics which seem to show that the elements themselves, or, at all events, some of them, are compound bodies. Thus it would appear that the hotter a star the more simple is its spectrum, for the brightest, and therefore probably the hottest stars, such as Sirius, furnish spectra, showing only very thick hydrogen lines, and a very few thin metallic lines, characteristic of elements of low atomic weight. On the other hand, the cooler stars, such as our sun, are shown by their spectra to contain a much larger number of metallic elements than stars such as Sirius, but no non-metallic elements; and again the coolest stars furnish spectra characteristic of compounds of metallic with non-metallic elements. These facts appear to meet with a simple explanation, if it be supposed that, as the temperature increases, the compounds are first broken up into their constituent elements, and that those elements then undergo decomposition into elements of lower atomic weight.

SCIENCE IN JAPAN.—Scientific men in Japan are now discussing the possibility of utilizing the internal heat of the earth. At a recent meeting of the Seismological Society, Mr. Milne read a paper in which he said that the fact that there was an unlimited supply of energy in the interior of the earth had been generally overlooked, although portions of it crop out in countries like Japan, Iceland and New Zealand, in the form of hot springs, solfatara, volcanos, etc. He stated that there is an unlimited supply of water in hot springs within a radius of 100 miles around Tokio, and that the heat of these springs should be converted into an electric current and transmitted to towns and business or manufacturing centers.

METEORIC HAIRSTONES.—At the late meeting of the British Association, Prof. Schwedoff said some startling things about hairstones. He made mention of one hairstone 26 inches in diameter, and of another as large as an elephant which took three days to melt. He advanced novel and startling views on the formation of hairstones. He contended that hail, exhibiting a regular crystalline form, and not infrequently falling from all points of the atmosphere, is not of atmospheric origin, generating from moisture suddenly in aerial storms, but that the stones come from ultra-terrestrial regions, and are, in short, a species of meteor of cosmic origin. Sometimes meteors were an accompaniment of hailstorms.

PROPOSED NEW SCIENTIFIC PHRASES.—Some scientific journals propose that men of science should be called "scientiates," and not "scientists," and that instead of using the phrase "scientific studies," we should rather employ "scientia studia." No doubt these changes would harmonize our expressions very closely with the Italian *scienziati* and *scienziati*, but it is exceedingly questionable whether the adoption of these new words would add much to precision of statement, when the words now in use have very definite meanings attached to them.

OBSTACLES TO THE CULTIVATION OF SCIENCE.—The *Popular Science Monthly* rightly says: "Two unregulated and overwhelming passions in this country stifle the growth of science—the intense and absorbing passion for wealth and the universal infatuation for politics. These are great national diseases, not peculiar to America, but malignant in America, and the state of mind they engender makes the systematic cultivation of scientific thought next to impossible."

SILICIUM INSTEAD OF CARBON.—Mr. Werdermann, whose electrical discoveries have attracted much notice, has just patented a new incandescent lamp. The peculiarity of this lamp consists in the fact that the vacuum, indispensable in all other such lamps, is dispensed with. Mr. Werdermann employs silicium in place of carbon, and he has succeeded in procuring from it better results than if carbon were employed.

COLD OR HOT GAS.—An eminent authority on illuminating gas, Mr. Sagg, insists that one point of great importance in the construction of a gas-burner is that the gas should not be heated until it arrives at the point of ignition. The body of the chamber below that point must therefore be made of a material which is a bad conductor of heat, to prevent an undue expansion of gas and maintain the heat of the flame.

JUPITER'S SPOT.—The great red spot on the planet Jupiter is reported by some observers to be growing fainter, with the prospects of an early disappearance. Others can detect no change. This remarkable object, nearly 30,000 miles in length and more than 8,000 in breadth, which has for more than three years maintained its size and shape without material change while moving across Jupiter's surface, is still a source of much perplexity to astronomers.

"PRESENT evidence," says Prof. Owen, in *Longman's Magazine*, "concurs in concluding that the modes of life and grades of thought of the men who have left evidences of their existence at the earliest periods, hitherto discovered and determined, were such as are now observable in 'savages,' or the human races which are commonly so called."

MASOOTE MINING CLAIM.—The Robinson Co. have purchased the machinery of the Ocala mine, on Squirrel creek, and have contracted with the well-known machinist Zeph Manna to set it up on the Masoote claim, in east Grass Valley, so that it will be known as the old Bulmer lot. It is proposed to give the claim a fair trial, and the appearance of the ledge and the expectation that it will make a valuable mine. Old miners in the district have an opinion that it may prove to be the true western extension of the once famous Eureka mine, for which much prospecting has been done. The new owners are the sons of "Old John Robinson," the well known citizen of Mr. George Murphy, who retains a third interest in the ground, is the superintendent of the mine.

ARIZONA MINE.—*Transcript*, Jan. 6th: The new 10-stamp mill at the Ariz. mine has been running for the last 3 days. The mill was constructed under contract by M. C. Taylor, the Grass Valley countryman, and is a first-class piece of machinery. It is furnished with four Flume concentrators. This mine has had considerable money expended on it in work of a prospective character. The main shaft is 600 ft. deep. At the bottom of the shaft, about 400 ft. below the surface, a small water course has been discovered. At the 400 level the ground has been pretty well prospected, the north drift being in 400 ft. and the south drift 250. On the 300 level the north drift has been run 630 ft. and the south one 300 ft. Three hundred ft. of crosscuts have been run at different points. The general average of the chutes thus far prospected is from 3 to 10 ft. in thickness, and varying in length up to 1,000 ft. At present it is difficult to run a crosscut through the drifts, but after a number of months or so some definite ideas can be formed as to the ore's value. The former owner intended to have had 2 or 3 crushing at cut-mills that paid from \$10.50 to \$33 a ton. The lateness of the season when the wood contracts were let renders the supply of fuel short, and until the weather settles and the roads get fit for hauling the work of development will be somewhat retarded. The property is well recorded here, and is being managed with careful and economical management. It will develop into a first-class mine. It now seems to be in good hands, Supt. James displaying energy and shrewdness coupled with a determination to do his duty. We shall more thoroughly discuss the mine's prospects hereafter.

PLACER.

ANOTHER MINING ENTERPRISE.—*Placer Herald*, Jan. 6: Wm. Werry, one of our thrifty and energetic mining men, has a force of men at work on what is known as the western extension of the Rising Sun mine, near Colfax. He proposes to work the ledge through a tunnel from the Bear River gage. This tunnel is now in about 200 ft., or nearly half the necessary distance. The old Rising Sun has been one of Placer's best paying quartz mines, and Mr. Werry, who was superintendent of the latter, has some time, has concluded that the extension is as good as the original.

THE PART AND FUTURE.—Except the injury to business caused by the hammering of our hydraulic mining industry, the year 1882 was a prosperous year for Placer county. The drift mines generally did well, and the quartz mining industry received quite a stimulus by the development of a number of comparatively new leads. Thus far the outlook for the year 1883 is altogether encouraging, except for our hydraulic miners. They have not yet had water enough to wash, and the threat that comes from below of enjoining them if they attempt to wash, makes their outlook anything but good.

PLUMAS.

NOTES.—*Oreenville Bulletin*, Jan. 3: There is not much of note to report in the mining interest this week. At the Cherokee there have been several sales under the attachments for labor and supplies furnished. The future of the mine and the old Silver Hill mine will be reported here by the current several times of some one coming from New York fully authorized by the directors to settle up the affairs of the mines with a view to resume operations, but no such person has yet appeared.

GREEN MOUNTAIN.—At the Green Mountain mine both the mills are running steadily. Stock papers in New York give very dismal accounts of the mine, but these accounts are very different from what is said of the mine by men who have the very best facilities for knowing its condition. However, it is a struggle between the stockholders and the stockholders; they can fight it out. The new air compressor lately received is nearly ready for work.

SAN BERNARDINO.

GARFIELD.—*Calico Print*, Dec. 30: Owned by Wm. Raymond. Two men at work on the ledge, which runs north and south. Ore assays \$500. Vein matter 7 ft. wide. A shaft 7 ft. in being sunk.

ALTAIR.—Work on this mine still progresses, and tons of first-class ore are being taken out daily. The returns of the last lot of ore taken to Sherman's mill averaged over \$800 per ton. A previous run went from \$400 to \$600; the last run averaged \$10 better than the same kind crushed at Oro Grande mill.

ORIENTAL MILL.—The work on this mill is progressing, and before many weeks it will be in operation. The boiler and engine are in place and the pump is being set in order. All the machinery is on the ground and the heaviest part of the work finished.

SILVER SPRING.—This promising mine has been bought by Messrs. Hunt, Daggett, Walsh and others, the amount paid being \$1,500. The Sherman mill has been leased for a month, and it is the intention of the company to put enough men on the mine to take out 10 or 12 tons a day. Last Christmas there were several men at work on the claim, and the showing continues to be good. There are 230 sacks of good ore on the dump and Mr. Benfield is making arrangements to have the same crushed at Sherman's mill.

BES.—This mine, owned by Wm. Raymond, is showing up well. A cut 14 ft. deep has been run 10 ft. into the ledge, from which ore has been taken assaying \$2,000 and working \$1,000 to the ton. Eight or 10 tons of ore are on the dump.

O. K.—Owned by Robt. Greer and Barrett. Situated near the Bismarck Assessment work is being performed. Ledge 2 ft. wide. Ore assaying \$100.

DEACON, No. 1.—Work has been resumed on this mine. On the northern side a tunnel has been run in 20 ft. On the southern side the shaft is down 20 ft. The paying streak is 10 inches wide, and the ore assays as high as \$1,000 per ton.

SHASTA.

CENTENNIAL MINE.—*Shasta Courier*, Jan. 6: One of the promising mines of western Shasta is the Centennial, owned by Russell & Co. It is located at the extreme head of Eagle creek, and about five miles from the noted Chico mine. The ledge shows a width of 6 ft. on the surface, and 4 ft. at a depth of 10 ft. The ore is principally silver, is almost entirely free from base minerals, and very much resembles the best and freest ore of the celebrated White Pine district in Nevada. The course of the vein is northeast, and it is found at an altitude of 3,500 ft. There has been 100 tons of ore taken out of this ledge, and tests by numerous assays give an average of \$75 per ton. The mine is being developed by several tunnels, the combined length of which is 425 ft. These can be run to a depth of 3,000 ft. below the surface, and without interference from inflowing water, and the facilities for dumping the ore direct from the tunnels to a splendid water-power is unsurpassed.

SIERRA.

SAVAGE PLACER MINE.—*Sierra Tribune*, Jan. 6: On the ridge between Forest City and the Savage mine the snow is now about 3 ft. deep. An effort was made before the mine was shut down to shovel out a trail, but with very little success, as the shovellers were obliged to wear snowshoes. To get 19 bushels of coal in the mine cost \$14, and other supplies in the same proportion. Some of the rock that was thrown out by the last blast in the face of the drift was rotten granite mixed with slate, and quite

soft. This drift is now in a distance of 692 ft. The drift is liable to cut into the second or main channel at any time. Jas. McNaughton, President of the Bald Mountain Co., and H. W. Wallis, Superintendent of the Bald Mountain, have examined the Savage ground, and say that the drift is a gravel drift, and that the gravel is merely an overflow from the main channel. The company is confident that when the main channel is reached paying gravel will be found. Everything at the mine will be kept in good shape until work is resumed in the spring.

TUOLUMNE.

FRUIT MINE.—*Tuolumne Independent*, Jan. 6: Dr. Blatchley, who is superintending and operating the Empire drift gravel mine, in Table Mountain, on Mormon creek, has supplied new track, put the tunnel up at heel, and huzg new the air-pipe to the extreme end, at the gravel channel. Two gangs of men are being worked respectively up and down the channel from the tunnel. The doctor gets \$1 to the pan, and says the chances for a "boom" are decidedly favorable. From the "perfectly marvellous" amount the channel has paid in different claims along the line in early days, we have no doubt that this virgin ground will surprise the owners and be the means of reviving like mining properties in other sections of the county.

NEVADA.

WASHOE DISTRICT.

OHIO.—*Enterprise*, Jan. 6th: The joint Mexican mine is now a few feet below the 3100 level. There has been no change of formation. The ground is not so soft that much better progress can be made in sinking. A sample of sufficient depth can be made in 8 or 10 days if the ground continues as at present. The material in the bottom shows some small feeders of quartz, and is quite favorable for the finding of ore, assays showing it to be fertile and metal-bearing.

MEXICO.—The joint Mexican Consolidated east cross at the 2000 level is showing some favorable ground, more than it has heretofore, and quartz feeders and stringers are beginning to appear in the face. A station is being cut out for a joint drift at the 2000 level. For work in the joint drift, now down below the 3100 level, see report on Ophir.

UNION CO.—The joint Mexican east drift on the 2000 level is passing into the ground which shows feeders and stringers of quartz. On the 2000 level are also cutting down the grade in the main drift. The station from which starts joint Sierra Nevada east drift on the 2000 level is being substantially timbered. All other work is progressing as usual.

UNION SHAFT.—Next Monday the work of taking out the present pumps and putting in those of larger size will be commenced. The present pump column will be allowed to remain, as it will carry all the water that can be raised from the large mine. The pump will be put in place at the shaft to be greatly increased at small expense.

CONSOLIDATED VIRGINIA.—The face of the east drift on the 2700 level is showing promising feeders of quartz. The work of overhauling the machinery is about completed, and the first of next week all the miners of the north end mines will pass down that way, pending the changing of the pumps at the Union shaft.

CALIFORNIA.—Progress is being made in the joint Consolidated Virginia east drift on the 2700 level. The face is in material containing many feeders of quartz. A drift is being run into the core, a drift's ground on the 2000 level. This is an extension of the drift which was run south across the Ophir.

HAIR AND NORCROSS.—The joint Savage north later drift on the 2000 level is being advanced as rapidly as possible toward the Savage south line. The face is in material showing a considerable amount of quartz. Thus far not much water has been encountered.

SIERRA NEVADA.—The east crosscut on the 2700 level is being pushed ahead as rapidly as possible and is going toward its resting ground. The joint Union Consolidated station on the 2000 level, from which starts the joint east crosscut, is being permanently timbered.

CHOLLAR.—The south drift is passing through vein material containing numerous seams of quartz, but of the kind that carries little metal. The drift is passing into a section where it is necessary to guard well against water.

GOLD AND CURRY.—The west crosscut is being advanced at the usual speed. The diamond drill was sent ahead last week to guard against water. The crosscut is going into a promising country lying out west in front of the foot wall.

SAVAGE.—The joint Hair and Norcross north drift, on the 2000 level is in soft ground of a favorable appearance. Some water is encountered, but not sufficient to interfere with the operations of the workmen.

ARIZONA.—The north drift from the winze is in very favorable material, and the east crosscut from the south drift is cutting quartz of a favorable character.

YELLOW JACK.—Are taking out about 60 tons of good milling ore per day from the old upper levels. The mine is now making regular shipments of bullion.

BRISTOL DISTRICT.

DAY MINE.—*Pioche Record*, January 21: In the Day mine is being steadily urged ahead and a full force is employed. The 800 level has been reached, a station cut and a drift started in the direction of the ore chamber, and work of sinking to the 600 level is now going on. The machinery has been overhauled, and the little engine is doing good work, it not being necessary to use any windlasses in attaining this depth. This property grows more valuable as work progresses.

ESMERALDA DISTRICT.

NEW MILL STARTED.—*Esmeralda Herald*, Jan. 6th: The most important event of the week in the vicinity was the starting up of the new mill at Gregory flat. Everything started off as smoothly and nicely as could have been wished for, and all at the noise of the falling stamps the po. Hags of champagne corks were let to burst, and men and boys were overjoyed. The day was a success when all returned to their respective abodes, fully satisfied with the starting up of the new mill, and wishes for it a long and successful run. Rejoice and be glad, for a brighter day has at last dawned upon this benighted people, and the star is once more in the ascendency. A portion of the building of the Silver Hill mill at Bodie was used, and the balance of the lumber was hauled from Hawthorne. The boiler, engine and parts of the Silver Hill mill were also used, while the rest of the machinery was obtained in San Francisco. The main building is 45 ft. wide by 80 ft. in length; battery-house and ore-house 33x43. The foundation of the engine is made of cut granite, and is 22 ft. long by 32 ft. deep and 9 ft. wide. Ten stamps, 4 pans, 2 rollers and 1 separator are now in use, giving a capacity of about 20 tons daily run. Mr. Barton put up the machinery and George Allright had charge of the building. They did their work well and satisfactorily.

CONCENTRATING WORKS.—Supt. McIntosh now has a force of 40 miners at work stopping out ore and prospecting. All of the stops are looking well, and yielding about the same quantity and quality of ore as usual. The inside workings of the mine are now arranged that no waste has to be taken out, it all being stored away. During the past month an ore-house has been erected at the mine, into which the ore is run on a car. Mr. McIntosh now has everything in and about the mine in fine working order, and is desirous of giving the country the best and most systematic and energetic control of the property. Through blivm and energy the Cortex now bids fair to soon become a bullion producer of no small pretensions.

JACKRABBIT DISTRICT.

NEW SHAFT.—*Pioche Record*, January 21: A large double-compartment shaft is being sunk on the Cotton-tail mine in Jackrabbit District, there being two shifts employed in the work. Lynch has commenced working this property in earnest, a thing which should have been done long ago.

PARADISE DISTRICT.

BULLION MINE.—*Virginia Enterprise*, Jan. 6th: J. V. McCurdy who has been superintendent of the Bullion mine and mill, Paradise, for some months past, arrived in this city, where he is family residing, a day before yesterday. Mr. McCurdy thinks well of the Paradise mines,

and will probably return again to flumbolt. The Bullion mine has been shut down for the present, owing to the bad condition of the roads, but there are several hundred tons of ore at the mill, and tailings sufficient to run it for some time. Mr. McCurdy says that in no instance, thus far, has any vein in that district disappointed its owners when they have expended a cent and labor in sufficient and intelligent prospecting operation.

THE LIVE YANKEE.—*Silver State*, January 4th: Nick Frayer is in town from the Paradise mines. He says they have struck the ledge in the Live Yankee tunnel at a depth of 325 ft. The vein is large, but the greater part of the ore is of a low grade, averaging about \$10 to the ton. There is a small streak of the ore which assays over \$3,000 to the ton, and the indications are that it will increase in size as the vein is opened. Mr. Frayer deserves success, and we sincerely hope he will attain it.

TUSCARORA DISTRICT.

BLACK LICK.—*Times Review*, January 4th: North drift, west vein, 350 level, extended 24 ft. Formation continues favorable for making rapid progress.

INDEPENDENCE.—Drift south on the 400 level has been extended 9 ft., total length, 241 ft. West cross-cut advanced 7 ft. No. 1 shaft has been completed to the depth of 200 ft.

NORTH BELLE FLS.—Since last report no work has been done on the mine, but the machinery is about completed, also the work on the boiler. Sinking of the shaft will be resumed in a few days, which will be continued to the depth of 400 ft.

ELKO CO.—During the past week the main drift at shaft No. 1 has been extended a distance of 8 ft. The formation continues hard. The ledge continues to widen and the ore improves in quality. Arrangements for sinking a new perpendicular shaft will soon be completed and better results obtained.

NAVADO.—South drift, east lateral vein, 350 level, has been extended 15 ft. It shows a large width of vein matter and small seams of rich ore. Crosscut on the 450 level has been extended 13 ft. Stopes are looking well. Drift on shipment of \$16,100.98 was made on regular shipping day, and for the month ending Dec. 31, \$85,194.83.

GRAND PRIZE AND ARIZONA.—East drift on 700 level extended 24 ft. total, 294 ft.; west drift, 17 ft.; total, 53 ft. North crosscut on 150 level, 15 ft. total, 35 ft. Ariz. vein 9 ft. total, 72 ft. in depth. Joint vein, 17 ft. total, 123 ft., following the inclination of the ledge. No change of formation in any part of mine, except an improvement in joint winze. Have taken out one of the steam pumps, and will have the plunger pump in and running all right by the last of the week, which will save a large amount of fuel and several men's wages.

TYBO DISTRICT.

BULLION.—*Bulmont Courier*, Jan. 6th: The Tybo mill is still running on ore from the 2 G mine. Considerable bullion was shipped during the past year from that camp.

WARD DISTRICT.

LIVELY.—*Pioche Record*, January 21: Ward is getting to be quite a lively place, and there are a good number of people there and the vacant buildings are rapidly being inhabited. Work of placing the mill in order is going on, but Mr. Poujade says it will not be in readiness to start up for several weeks yet.

ARIZONA.

BIRNEY.—*Cor. Epitaph*, Jan. 4: The history of the past year shows a great deal of material improvement, a great deal accomplished fact that was a year ago contemplated, and a confidence in the future, if ever in any degree impaired, restored and greatly augmented. The Copper Queen, then a giddy young thing that people feared had no depth to her, has settled down to business, been a regular producer ever since, and demonstrates her right to the supremacy she has won. This mine is probably the best developed silver property in the Territory to-day, with every probability of continuing to be so for years to come. She may not pay such large dividends as some, but that is only because a greater force from her present development a prodigious amount of copper per month if her owners chose. But they are well satisfied with the present excellent, judicious and economical management of their property. The Silver Bear, about a mile and a half from the Queen, is also a fine mine. For several months she has been producing rich ore. It is said that all the expenses of working the mine have been paid from the ore extracted, and this ore had to be hauled a distance of miles for reduction. The Queen considered the best, although until now lying undeveloped. Besides these the Black Jack, the Holbrook, Cave, Ulio Sam, Della Mack, White Tailed Deer, and a score of others show enough in prospects to encourage the belief that there will one day be the greatest mining camp in Arizona. Our population has not greatly increased, but there are indications that those who are here have come to stay. The tents have given way to commodious houses and cabins.

WASHINGTON.—*Idaho News*, Jan. 2: The shaft of this mine is about 700 ft. due north of the Silver King mine, and is down 45 ft. on a ledge dipping 45° towards the Silver King mine, on pay ore all the way down from the grass roots, very much resembling the Silver King ore as that was ore and the best of the kind. The ore is all along the surface the entire length of the claim, which runs northeast and southwest, and over on to the ad. being claim on both sides. The vein is narrow, averaging about 4 inches, but very rich. Wages and expenses can be taken out at once. The character of the ore is of the best, clear and galea.

THE THEODORE.—The shaft work on this mine has just been completed. It is about a mile north of the Silver King mine, on the Ir. leading to the Mount View, and is situated between the two main veins, which are 6 ft. apart. The shaft is about 700 ft. deep, and the ore is all along the surface. Some fine quartz and promising ledge matter were taken from the mine. There is a splendid prospect for a big mine on this claim, as several veins cross it, which it is the intention of the owner to sink out when they shall have attained sufficient depth in the perpendicular shaft which they are now sinking.

OWL HEAD DISTRICT.—The Jesse Benton mill is running on ore from the Desert mine, ledge 10 ft. wide, yielding large quantities of bullion. The mill is owned by W. H. Merrill, working mine and mill with economy and good judgment. They are getting very rich ore in the Jesse Benton, but it is rebellious, and they let it till they can adopt a better process for working it. The mill is doing well, the Chit mine, sinking an incline shaft, showing good ore.

COLORADO.

THE INDEPENDENCE.—*Colorado Miner*, Jan. 6: J. P. Williams, of Denver, largely interested in the mine claims here and around Deatur, came up from Denver last Friday night to take charge of the Independence mine on McElhann mountain. It is proposed to open up the property, which already has made a record for producing large supplies of good ore, in thorough, systematic manner. Mr. Williams is a miner of long and varied experience, having been engaged in the business for 28 years in Australia, New Zealand and America.

OVER THE RANGE.—Mr. Joseph A. Love returned from a trip over the range on Tuesday last, where he has been doing Chace work on some of his mining property, and says of that section and the roads: There has never been so little snow in the range at this time of the year as at present. From the Horse Shoe to Montezuma the snow will not average a foot in depth. The weather is quite pleasant, and outdoor work has been pursued all winter. A few people are working in the Snake River valley, who are working the mines. The Horse Shoe Mining Co. are employing a number of men, as also are the owners of the Captain Jack. Large quantities of ore are being taken from the latter. Nine men are employed in the Deatur mine, mostly on the ground work. They have 150 tons of first-class ore, and several hundred tons of concentrating ore. The new mill at Deatur is employing 18 mechanics in putting in machinery, and the company expect to start up work about the 1st of April. All the people who are living there are contented and satisfied with their future prospects. At Montezuma a large number of men are engaged in working the mines, and are shipping about 50 tons of ore per week to the South Fork railroad for transportation. The Leadville, which costs \$100,000 for transportation, carrying freight and passengers. Between 100 and 200 men are working between Haywood's and the forks of the Snake river. The road is surveyed and located to Montezuma. It is expected that cars will reach that point early next summer.

IDAHO.

WOOD RIVER.—*Cor. Idaho Statesman*, Jan. 6th: Our people cannot tell when the snowfall commences, when it will end, and consequently when we will have a snowfall of 11 inches during the early part of October. All the teams that were engaged in hauling ore, wood and lime to our smelters, became alarmed, and left-making it necessary to close down. Soon after the teams left, the weather became warm, and has remained so ever since. The snow is now about 10 inches deep, which shows the work of the Kellogg smelter for a given time, with the loss of last week it closed, and you can see how much we are loser. Here are the figures, which are official: The Philadelphia Co., at Ketchum, operated ore, 40 tons furnace, about 3 months during the past season, and at that time put through 4,250,350 lbs. of which yielded 1,575,257 lbs. of lead and 165,879 ozs. of silver. Of this amount, 1,493,913 lbs. giving a yield of 510,165 lbs. of lead and 47,228 ozs. of silver, were from mines operated by this company. They purchased outside ore to the amount of 1,420 tons, which yielded 1,685,992 lbs. of lead and 118,183 ozs. of silver. Thus you will see that the teams remained on the work gone on without interruption, for 3 months, and we would have had an additional output of at least \$50,000, and one-half of which would have been expended here for team hire and labor. It can be readily seen what a difference this would have made in the circulating medium of this country, and this is one of the many interests which have suffered by that storm. It is no wonder that 100,000 would not more than make this country even on the damage sustained. But we are doing the very best we can under the circumstances. It will not do for a mining community to let go, and "cry over spilled milk." Every one seems to be doing the very best he can to amend the misfortune. Mines are being opened, ore taken out and piled on the dump; assessment work is being done, and preparation for the spring. All seem to be of the opinion that the summer of 1883 will be one of great prosperity in this country.

MONTANA.

STIRKE IN THE SHONBAR.—*Inter-Mountain*, Jan. 5th: During the past few days Joseph La Calf, Judge Warren, Judge Barrett and other owners in the Shonbar, have been highly elated over developments in that rising property. At a depth of 85 ft a drift was started east on what was supposed to be the main ledge, which it followed for a distance of 125 ft. At this point one of an entirely different character was struck in a vein trending northward, and of which what is thought the old ledge is merely a spur. The ledge is yet unknown in width, but the ore body measures 31 ft wide and samples 107 ozs in silver and 2 ozs in gold, giving the ore a total valuation of \$150. A 3 ft body of \$150 is a big bonanza in any country. La Calf is quite certain that he has hit all along in working the ledge, and that the vein is just discovered in the 150 ft east drift will develop into a veritable bonanza.

A NEW BONANZA.—*Helena Independent*, Jan. 6th: Several weeks ago Dr. F. Remington, of Lincoln, Deer Lodge county, gave Mr. C. E. Kemp two samples of ore to be assayed. The ores assayed in gold and silver about \$1,720, and \$1,330 per ton. From a letter received yesterday by Mr. Kemp from Dr. Remington, in relation to the mine from which the samples were taken, we make the following extract: "The mine from which sample No. 1 was taken, is located in the mountains, and I cannot possibly get any more ore for a larger test sample until spring. I had some more ore, but it was lost when our house burned down."

NEW MEXICO.

TELEGRAPH DISTRICT.—*Silver City Enterprise*: The people of the Telegraph district are talking of building a road from their camp to Rich's ranch, on the Lordburg road. Almost every miner in the district has agreed to do a certain amount of work on the road or to have some one to do it in his place, and the Lordburg merchants are taking of subscribing money to aid them in the enterprise. This step is being taken because there is no road leading to the mine at present, and goods taken there from Silver City or from Lordsburg are very expensive. The road will be packed on burros for about two miles. Lordsburg is at present the nearest point on a railroad to Dursey's camp, but when the Silver City, Deming and Pacific Railroad is completed, this station will be at least 20 miles nearer. This district is an exceedingly rich one, and the population will probably increase rapidly.

OREGON.

NOTES.—*Jacksonville Times*, Jan. 6: Berryman & Hansen, of Applegate, continue drifting to good advantage, in spite of the cold weather. S. A. Borough, of Sale Creek, showed us some specimens of iron ore found in that section. The weather is more favorable for mining, and it is said as the cold spell seems to be broken, and some snow and rain have fallen in the past day. The cold snap has put a stop to mining operations, but it is not likely to last long. More work is needed to facilitate drainage in this line, however. R. W. Derickson came over from Horseshoe, Josephine county, this week, and reports that considerable gold is being taken out right along. The miners of Josephine county have been favored with much more rain than the others, besides, the weather has been so cold there, and many are busy at work already. Geo. Ross, who was up from Blackwell this week, informs us that Welch & Co's mill has been put in excellent running order, and will soon be crushing ore at a high rate of activity. Hanna has been in Josephine county locating iron mines for himself and others. He returned Thursday, accompanied by Sam Bowden, bringing some fine specimens of ore with him. Geo. Simmons' mammoth ditch has been completed by him. The mine is to be high for several days this season, operations will be suspended for the present. Mr. S. expects to have this mine in full blast next winter.

UTAH.

NOTES.—*Salt Lake Tribune*, Jan. 7th: Yesterday the Sampson mine at Park City struck in the Van Frazer incline a solid body of rich ore over 2 ft wide, assaying up to \$1,000 per ton. The mine is located southeast from the Crescent group. The Utah Central carried 102 1/2 tons of salt to Ogden during the year 1882 for shipment to Park City, Colorado, Montana, etc. During 1882 there was received at Ogden by the Utah Central from the south, 1,969,767 lbs. of 50,482,633 lbs. base bullion, 7,140,26 lbs. lead and 881,329 lbs. copper matte. The formation of new corporations and sale of property. Numerous valuable claims in Utah and Idaho are now being negotiated for, and we expect to see a big boom in mining matters soon. The Germania lead works will begin the manufacture of white lead in a few days, the machinery and works being almost completed. Miners feel greatly encouraged over the minor output in Utah. The steady increase in the bullion production gives them new courage.

CHAPARRAL PULVERIZER.—There is for sale in this city, as will be seen by our advertising columns, a second-hand Rutherford pulverizer, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it.

IDAHO AND MONTANA mine owners are preparing specimens for the Amsterdam Exposition.

TELEGRAMS announce that the furnace of the Pinal Consolidated mine, in Arizona, has again been started.

COPPER QUEEN produced 2,107,130 pounds copper during the three months ending November 30th, the value of which is estimated at \$400,000.

The Denver Exposition—No. 22.

[Editorial Correspondence.]

Arizona.

West of New Mexico, and occupying an immense region of country extending from the western flanks of the Rocky mountains to the eastern foothills of the southern point of the Sierra Nevada, is the Territory of Arizona. It embraces the southern rim of the Great Salt Lake basin, through which, in the northeastern portion of the Territory, the Colorado river has cut out its famous "Big Canyon," plowing its way down through the high table-land of that region, in many places from three to six thousand feet deep.

The Physical Features of the Territory

Are quite unlike any heretofore described in these letters. It has no great mountain range extending through its Territory or flanking either of its sides. It consists of an elevated plateau, gradually sloping in a southwesterly direction from an altitude of 7,000 ft. in its northeastern corner to that of only 100 ft. at Yuma, near the mouth of the Colorado, in the southwestern corner of the Territory. Isolated and parallel mountain ranges of inconsiderable altitude above their basis extend over this plateau in a northerly and southerly direction. The main ranges through the central portions of the Territory are composed of granite, porphyry and slates. The most important mountain range is the San Francisco, which is dominated by a great volcanic cone, 12,500 ft. high, in the northwestern portion of the Territory, and from which mountain spears of volcanic origin or plutonic upthrow diverge in various directions. Many narrow valleys, and now and then quite wide and open plains, occur between these mountain ranges. Here valleys are, many of them, rich and well watered and covered with an abundance of numerous grasses, and some of them highly cultivated.

Its Early History.

Hundreds of years ago, even before the Pilgrims landed at Plymouth, the early Spanish adventurers pushed their way into this region and found these valleys and plains the happy home of a quiet, industrious and semi-civilized people who tilled the soil, and to some extent worked the mines for gold, silver and copper. The Spanish thirst for conquest and gold destroyed those homes and scattered those people until merely a degenerated remnant was left. After a Rip Van Winkle sleep of some two centuries, the inhabitants of this region have again been disturbed by the appearance among them of a new but more progressive and utilitarian people, bringing with them the same old thirst for gold indeed, but with it, instead of the weapons of war and pillage, they bear the implements of peace, at least to all who seek and love peace and progress. The industrious Pima is protected in his rights of person and property, while the Ishmaelistic Apache, whose hand has ever been against every other man's hand, is justly hunted down without mercy.

The very name of "Arizona" has, perhaps by association, become suggestive of golden nuggets, streams yellow with golden sands and mountains rich in precious minerals. The origin of the name and its signification are somewhat doubtful. Some say the word signifies "The blessed Sun," from two Indian words, which, in the Mohave dialect, are *ara*—blessed, and *Zuma*—sun. Others derive the name from two Pima words—*air*, a maiden, and *zon*, a valley, in reference to a traditional maiden queen who once ruled over all the branches of the Pima race.

Arizona was set off from New Mexico in 1863, and the name first adopted was "Pimieria," which was soon dropped for the more euphonic and appropriate one which it now bears, and which was originally and still continues to be borne by a mountain near the southern line of the Territory. The history of this region has been a series of fierce struggles with the savage Apache. The intrepidity, daring and self-sacrifice of the early Territorial pioneers, who won this rich domain, foot by foot, from the savage race which dominated it at the time of their coming, is yet to be written, and when presented to the world will form one of the bloodiest pages in the whole history of American frontier life.

The earliest mention of this region in history is connected with stories of the unbounded wealth which it was even then supposed to contain. Probably the first European who ever set foot within the present limits of Arizona were the four men whom the Spanish navigator, Narvaez, left on the then unexplored coast of Florida in 1538. These men sought, by an overland journey across the continent, to join their fellow countrymen, who were established at Culiacan, in Sinaloa, Mexico. This remarkable journey was safely accomplished, their wonderful adventures told, and the riches of the country, and especially of the "seven cities of Cibola," portrayed in such glowing colors that an expedition was immediately sent out to visit them in force. This expedition was not unlike that of the ancient Argonauts who went in search of the "Golden Fleece." If the leader, Coronado, failed to bring back the rich treasure of which he went in search, he at least discovered and made known to his countrymen a land abounding in the precious metals, from which they afterwards reaped untold wealth. The old shafts and tunnels which have been discovered in various parts of the Territory give ample

proof that the early Spanish adventurers had fully proven the richness of its mines, and had, in their crude way, worked them largely and successfully. The same evidence exists that a still earlier race of miners once delved for the precious metals in this region; but neither Tolttec nor Spaniard were able to fully appreciate the riches and blessings of this wonderful land, which, almost in their entirety, remained hidden in the mountain fastnesses, until, in the progress of events, they are now being brought to light and usefulness by a race which can fully appreciate their value, and which is developing and dispensing them, not for personal, kingly or priestly hoarding, but for the general good of humanity and the world, and for the building up of another great, prosperous and powerful State in the American Union of States. Arizona is indeed

A Land of Marvels

For either the prospector, the scientist or the eight-seeker. Nowhere on the globe, unless we except the Black Hills of Dakota, heretofore described, can the operations of nature in building up the earth's crust be more clearly traced and described. While the upthrust of the Black Hills has laid open for our inspection and study the book of nature almost to its bottom page, here the stupendous gorges and deep and murky canyons of the Colorado have been so excavated, and to such a depth, that the geologist and mineralogist has only to enter and read upon the broad and massive leaves of nature the records of countless ages which have been impressed upon them in a language and with signs which no man need misinterpret or fail to understand.

The Territory of Arizona is one vast mineral field. In no other State or Territory is there such a universal and extensive distribution of all the minerals which enter into the commercial operations of the world. Every county in the Territory, save possibly one—Apache—a name significant of utter worthlessness and abhorrence—whether the fact is due to the name, to the feared presence of the savage whose name it bears, or to its own rough and rugged topography, we know not, but we are credibly informed that less prospecting has been done in Apache than in any other county in the Territory, and that, too, notwithstanding its indications of mineral value are by no means unpromising. Nature seems to have been especially lavish here in scattering her treasures, and has neglected no portion of this wonderful land, or favored one part above another.

No portion of the Rocky mountains or Pacific mining regions have yielded any greater variety or richer ores. Arizona has produced the largest nugget of native silver ever found upon any portion of the globe—a mass of pure silver weighing 2,700 pounds, which was confiscated by Philip V. of Spain and taken to Madrid. This act was soon followed by the absolute confiscation of the mine itself. It is not uncommon to find silver ores in Arizona which run up to thousands of dollars.

Arizona's Display of Ores at Denver.

In richness and variety, had no superior at that great show of minerals. The *Republican*, of that city, spoke of it as follows: "Considering the recent opening of the Territory, and the bonanza mines, Arizona takes a high rank among the mineral regions of the West, and gives promise of rivaling Colorado in its bullion production when the country is as extensively developed." It includes as large a variety of minerals, and combines the useful with the beautiful in a greater degree, perhaps, than any other exhibit at the Exposition.

The exhibit, besides being exceptionally good, was scientifically arranged, the different variety of ores from the various mines being carefully classified in separate cases, and so placed as to permit of ready inspection. There was no special effort made for mere display. The exhibit comprised specimens from over 400 different properties, from almost all parts of the Territory, whose combined weight was eight tons. The most notable special display was probably that from the Silver King mine. Some of the oxidized copper ores from that and other mines were undoubtedly the finest ever seen. The Tombstone district also made a most notable display. But we have no room for special notice of the various exhibits. One word, however, is due to Prof. J. A. Church and T. R. Sorin, the Commissioners representing the Territory, and for the industry, intelligence and ability displayed by them in the discharge of their duties. No men could have acted more intelligently or filled their places more efficiently. Their attention to visitors was untiring.

Cochise County

Has perhaps become more famous than any other county in the Territory, chiefly from the most remarkable development made within the past two or three years in the district.

Tombstone District.

The region of country comprised in this district has a history quite as dark and gloomy in character as the name which it bears. This region was the chosen retreat of the famous Cochise and his bloody band of warriors, and it is marked all over with the graves of his white victims. The first mining location here was the "Old Bronco Mine," known to be rich long before "Tombstone" had a name, and from which it is distant about six miles. Within the "dark and bloody ground" about this mine it is said no less than sixteen white men have met their death at the hand of savage Indians.

When in the fall of 1877 Mr. A. E. Sheifelen, the discoverer of this district, made frequent trips from Camp Huachuca alone into this neighborhood he was repeatedly told that if he continued his prospecting there he would find a tombstone instead of a mine of wealth; but he still persisted in his hazardous wanderings, and when, in time, he succeeded in finding what he sought, he perpetrated the grim joke of his friends by insisting that both the district and town should be named "Tombstone." The wonderful richness and extent of the district soon spread far and wide and attracted thither a large population, so that within three years from the discovery the town numbered fully 7,000 souls, and the district is one of the richest and most prosperous on all the Pacific slope.

The mineral belt of Tombstone embraces a region of about eight miles east and west by five north and south. The geological formation is porphyry, capped at most of the leading mining camps with lime. The ores of the district are rich and easily worked.

The present output of bullion in the district is about \$600,000 per month, from 140 stamps. This output is continually on the increase as these mines are more fully developed. This is certainly a good showing for a three-year-old camp. Some of the mines have been opened to a depth of something over 500 feet, at which point but very little water is found. There are over 3,000 locations in the district. The ores are mostly free milling silver ore.

This district was well represented in the Exposition by a large amount and great variety of its characteristic ore and rock. The ores are so rich that in several of the mines nearly one-half of the entire yield is disbursed as dividends. The reports of the aggregate yield of the Tombstone district almost challenge belief. The dividends alone from 54 mines for 1881 amounted to \$2,290,000. The dividends from only 43 mines in 1882, all the official reports we have before us, amounted to \$2,087,500. It is said that all the mines from which the above amount was realized were at one time bonded to well-known capitalists of this city for \$90,000, and that the bond was allowed to lapse. However that may be, the mines are now in the hands of good managers, who are working them under a conservative system, with good bodies of ore constantly opened up in advance; and it is predicted that ere five years have passed Tombstone will have developed mines sufficient to more than double her present population. We shall refer to other localities in our next.

W. B. EWER.

THE EUREKA CON. LAVA BEDS.—Concerning these beds the *Ruby Hill Mining News* publishes the following: Perhaps the most remarkable place in connection with our mining industry is the old Wintelz works, which is a part of the Eureka Con. mine, and which is commonly known as the "lava beds." A little over three years ago some miners conceived the idea that ore did exist in these old workings. The place had been abandoned by the company for a period of over two years. These men, having secured permission, commenced operations on the tribute system, and were highly successful. They were followed by others, until at one time there were nearly 30 men working there, all of whom made good wages, while not a few made nice little stakes of several thousand dollars, with which they left the camp for a more congenial clime, and are now living on the fruits of their labor and luck. At present 24 tributaries are working at this place, and we believe that \$4 per day has been averaged by these men. During the time that this place has been worked by tribute nearly a quarter of a million of dollars has been extracted from this once abandoned place, and it looks good now.

BAD MANAGEMENT.—The Investigating Committee—M. J. McDonald, R. H. Rodgers, Marcus R. Hall and Coll Deane—of the San Francisco Stock and Exchange Board filed a report, in which it states: Relative to the Ballion Mining Company the committee says: "We find no work has been done on the mine for about 10 months, and it is now in charge of a watchman. We consider the management of the mine recklessly extravagant and characterized by a total disregard of the rights of stockholders. The Belcher and Crown Point mines have produced, in about 20 months, 96,611 tons of ore, of the value of which we have no certain knowledge, for which the company received \$50.25 per ton, and these mines are still producing about 5,000 tons per month. We do not hesitate to say that these two mines are managed badly, and with a total disregard of the rights of the stockholders. And we further add that we consider the proxy system one of the greatest evils in the business, thereby enabling people to control mines and run them in their own interest who do not own the stock."

QUICK DRIFTING.—The Prussians have discovered that the best way to make rapid advance in drifting in mines is to pay each gang of men separately for the work done, the gangway being measured at the end of each shift. This involves considerable trouble, but results in rapid work. At the Anzen coal mine, in a bed dipping 8° to 10° and 4 ft. thick, a gangway 3 ft. wide was driven 203.5 yards in 26 working days, or nearly 8 yards a day. The work was divided in four shifts, three miners and one trammer in each shift, or 16 men in all. These men also laid track and put in the few timbers required. The work was done on the system referred to.

HOW WOOD IS HOISTED OUT OF THE CARSON RIVER.—The *Lyon County Times* gives the following account of a Nevada invention for hoisting floating wood out of the water: The Carson wood drive is being rapidly taken out of the water. Some distance above the boom wagons are at work, and the hoisting machine at the boom is doing good work. Mr. Cameron intends, in the course of time, to arrive pretty nearly at perfection with his invention. Each time the machine comes here it has improvements added which give it greater efficiency. When first made the wood was carried up the endless chain and thrown over into a cart, and when one cart was full work had to stop until another took its place. A movable apron, or slide, has been added, which extends to a framework across the road, where the first cart stands. The apron is hinged on to the frame and held up while the cart is being filled, and then dropped to receive the wood which slides over it to another cart stationed outside the frame. While the outside cart is receiving its load another takes its position on the inner track, and at the proper time the apron is lifted and the wood again falls directly from the end of the elevator. In this way a continuous procession of cord wood moves out of the river over the endless chain, and no stoppage is required except to repair breakages or oil machinery. It is an excellent contrivance for the purpose, but is especially valuable in cold weather, as it saves the necessity of half a dozen men standing in the water up to their waists for hours while loading wood on the wagon.

HOW MUCH DOES YOUR CISTERN HOLD?—

It is a difficult matter for the average man, who does not make mathematics a specialty, to compute the capacity of a cistern. For the benefit of those who may want to make such estimates we give the following by W. H. White in the *Country Gentleman*: Knowing the capacity of a gallon in ft. and inches, it is an easy matter to calculate the capacity of any sized cistern. A cubic foot of water is seven and one-half gallons. Knowing the cubic ft. in any cistern, by multiplying that by 7½, we find the capacity in gallons. The number of cubic ft. in any rectangular cistern is found by multiplying the length, breadth and height together; the product multiplied by 7½, as above, gives the capacity in gallons. For a round cistern I give the following table as convenient for reference: A cistern 5 ft. in diameter contains 19 3-5 cubic ft., or 147 gallons for each foot in depth; 6 ft. across, 28½ cubic ft., or 212 gallons; 7 ft. across, 38½ cubic ft., or 288 gallons; 8 ft. across, 50½ cubic ft., or 376 gallons; 9 ft. across, 63½ cubic ft., or 476 gallons; 10 ft. across, 78½ cubic ft., or 589 gallons; 11 ft. across, 95 cubic ft., or 712 gallons; 12 ft. across, 113 cubic ft., or 847 gallons. From this may be easily calculated the diameter and depth of a cistern to hold any quantity of water desired.

A GOOD razor paste is made by mixing fine emery intimately with fat and wax until the proper consistency is obtained in the paste, and then rub it well into the leather strap. Prepare the emery by pounding the rather coarse material in a mortar, throwing the material into a vessel of water and stirring well. Immediately after the large particles have sunk pour off the supernatant fluid into an evaporating dish and evaporate off the water. Another recipe is: Emery, reduced to an impalpable powder, two parts; spermaceti ointment, one part; mix together and rub it over the strap. Another is: Jewelers' rouge, blacklead and suet, equal parts; mix and rub it over the strap.

UNPLEASANT TASTE FROM WOODEN VESSELS.—It is often found desirable to remove the unpleasant taste which is frequently observable from new wooden vessels. This is often a thing difficult of accomplishment. An exchange suggests that the simplest plan, and one that will succeed in most cases, is to scald them thoroughly several times with boiling water; then dissolve some pearlash or soda in luke-warm water, adding a little lime to it, and wash the inside of vessels well with the solution. Afterwards scald them again thoroughly several times with boiling water as before.

SECRETARY TELLER has amended the placer mining claim circular of Sept. 22d so that it provides that no application by an association of persons for a patent to a placer claim will be allowed to embrace more than 160 acres, and not less than \$500 worth of work must be shown to have been expended thereon. If an individual becomes the purchaser and possessor of several separate claims of 20 acres each or less, he may include in his application for a patent any number of such claims contingent to each other, not exceeding 160 acres.

ELECTRICITY IN BELTS.—Some of the larger belts in an extensive Western flour mill have been provided with wires to receive and conduct away any surplus electricity that may be generated. Where the belt passes through the floor a wooden cleat is nailed across the opening on the outer side of the floor, an inch or two away from the belt, and to the cleat, pointing out toward the belt, are fastened prolonged hrads, which take the electricity from the belt, the latter being conducted away to water mains by means of wire connected.

The Tariff on Lead.

(CONTINUED FROM PAGE 18.)

higher-grade silver ores, which would be produced after the reduction of the tariff, making a total loss to the laborer, the furnisher of supplies, the mine owner and the smelter of this camp of about two million eight hundred and forty thousand dollars (\$2,840,000) per annum.

This threatened loss is based only on the present output of this camp. The concentration of ores, which is just now receiving the attention of capitalists, and can be carried on successfully with the present tariff, must be abandoned in case of a reduction of the tariff. There is enough of this ore now on the dumps on the various mines, and known to exist, to assure an output of at least 500 tons per day. The profit on these concentrates would be small and would not exceed a fair per centage on the capital invested, but their production would add about \$2,500 per day, or \$750,000 per annum, to the amount expended in this camp for labor and supplies. The profit from these concentrates is estimated at \$200,000. These two sums, added to the sum above given as the threatened loss, show an annual loss of \$3,790,000 to this camp alone, which would fall on the several classes as follows: Laborers, \$2,150,000; furnishers of supplies, \$750,000; and capitalists \$89,000.

To this extent the immediate consequence of the proposed reduction of the tariff on this camp can be traced in figures. Some of the remoter consequences, which will prove none the less disastrous, though they cannot be stated in figures even approximately correct, are the following:

The amount of

High-Grade Ores Produced

Has been and is steadily diminishing. The known bodies of ore that cannot be mined with the reduced tariff already exceed in amount and value the known bodies of high-grade ore. The most reliable mines to-day are the low-grade mines. Hence, the injury resulting from the proposed reduction of the tariff would steadily increase.

Large bodies of low-grade ores that are now penetrated in search for better ores, because the ores taken out in prospecting will pay the expense of the prospecting, will be abandoned if the tariff is reduced, whereby the chances of finding richer ores will be greatly diminished.

Of the 90,000 tons of ore above mentioned as ore that would not be mined in case the tariff is reduced, 60,000 tons are from mines that carry no high-grade ores and would have to shut down. The value of these mines and of the extensive improvements connected therewith would be wholly destroyed. The shrinkage of value in mining property in this camp will exceed the sum of \$5,000,000. Smelters will be similarly affected.

A decreased demand for labor will not reduce wages. The superfluous labor will leave the camp. A decreased demand for supplies will tend to advance their price. Railroad freights will advance if the bulk of the freight is diminished.

The Producer will Suffer by the Reduction. The consumer will gain little, because the reduction is not sufficient to materially affect retail prices. The only real gainers will be the owners of the Spanish lead mines and the foreign shippers.

A reduced tariff will admit foreign lead. The foreign producer would thereupon agitate further reductions of the tariff, and thereby keep the lead market in a state of fever that would check, and eventually destroy, home production. Note the decline of lead produced by the present agitation.

The reduction of the tariff on lead ores by one-half cent per pound, or \$10 a ton, would be even more disastrous than the proposed reduction of the tariff on manufactured and pig lead. The abolition of the tariff on lead and lead ore would be ruinous to the interests of this camp.

The undersigned, though they cannot speak in figures for other camps in this State, know that the proposed reduction of the tariff on lead and lead ore would affect every section of this State, more or less, in the same manner, and must operate as a material check upon the development of the resources of this State, and a blow to the present prosperity of its inhabitants. It is believed that no member of the Tariff Commission, owing to the limited time allotted the Commission for the completion of its labors, was enabled to come here and examine the conditions of our lead industry.

Wherefore the undersigned, on behalf of themselves and of the residents of this camp, respectfully, but earnestly, protest against any reduction of the present tariff on lead and silver ore, pig lead and manufactured lead. [Then follow the signatures.—EDS. PRESS.]

A NEW DYE.—The young growth of the poplar tree yields a dye, to which we have before referred, which may be extracted as follows: The young twigs and branches are bruised and boiled for twenty minutes with a solution of alum, 10 pounds of wood requiring 1 pound of alum, in 3 gallons of water. The solution is filtered hot and allowed to cool, and, after standing some time, is again filtered from a resinous deposit. On exposure to air and light it develops a rich gold color, and may be used directly for dyeing orange and yellow shades upon all classes of goods.

USEFUL INFORMATION.

How to Judge of Good Grinding.

Catch your hand full of the meal as it falls from the stones, and feel it lightly between your fingers and thumb, and if it feels smooth and will not stick much to the hand, it shows it to be fine enough and the stones to be sharp. If there be no lumps to be felt larger than the rest, but all of one fineness, it shows the stones to be well faced, and the furrows to have not too much draught, as none has escaped unground. But if the meal feels very smooth and oily and sticks much to the hand, it shows it to be too low ground, hard pressed and the stones dull. But if it feels part oily and part coarse and lumpy, and will stick much to the hand, it shows the stones have too much feed, or are dull and badly faced, or have some furrows that have too much draught, or are too deep, or perhaps too steep at the back edge, as part has escaped unground and part too much pressed and low. Catch your hand full, and, holding the palm up, shut it briskly; if the greatest quantity of the meal fly out and escape between your fingers, it shows it to be in a fine and lively state, the stones sharp, the bran thin, and will bolt well; but the greater the quantity that stays in the hand, the more it shows the reverse. Catch a handful of meal in a sieve and sift the meal clean out of the bran; then feel it, and if it feels soft and springy or elastic, and also feels thin, with but little sticking inside of the bran, and no pieces found much thicker than the rest, it will show the stones to be sharp and the grinding well done. But if it is broad and stiff, and the inside white, it is a sure sign that the stones are dull or overfed. If you find some parts that are much thicker and harder than the rest, such as almost half or quarter grains, it shows that there are some furrows that have too much draught, or are too deep or steep at the back edge, else that you are grinding with less feed than the depth of the furrows and velocity of the stone will bear.

Efflorescence on Brick Walls.

The Philadelphia Times mentions that the white efflorescence on brickwork, known to the ignorant as "salt-peter" has been particularly common in that city during the present season, several old buildings which had long been free from it showing as much incrustation as those of very recent construction. A reporter seems to have been enterprising enough to question Dr. Joseph Leidy, President of the Academy of Natural Sciences, upon the subject, and repeats with remarkable correctness what is certainly the true explanation of the phenomenon. According to Dr. Leidy, the efflorescence is composed of sulphate of magnesia, which is in most cases easily shown by analysis, and is produced, he thinks, by the action of the sulphurous acid, always contained in the air of cities, upon the magnesia salts in the mortar with which the bricks are laid. There is, we believe, some doubt whether the sulphurous and sulphuric acid of the atmosphere alone is sufficient to produce the effect. It is always observed that a wall, the top of which is exposed to the rain, or which receives water into its interior in any other way, soon shows a copious efflorescence, as if the magnesia salt was dissolved in the heart of the wall and brought to the surface by the evaporation of the water, so that some imagine that the coal used in burning bricks about Philadelphia and other sea coast towns may leave a sulphurous deposit within their pores, which acts on the lime, or rather on the cement, with which they are built.

In the above Dr. Leidy expresses the correct explanation of this annoyance, which we gave some time since in the Notes and Queries department of this journal. It is unquestionably due to the action of sulphuric acid on the magnesian mortar commonly used in Philadelphia. The action of sulphuric acid from coal-burned bricks is quite subordinate to the other.

BOILING WATER IN A SIEVE.—If we cannot carry water in a sieve, science has told us how we may boil it in such a vessel. There are numerous ways in which this curious experiment may be performed. One of the simplest is the following: If the open mouth of a glass bell-jar, of any diameter, from 10 to 20 inches, be closed by means of a piece of coarse muslin and then depressed into a vessel of water, the water may be drawn up into the bell jar by aspiration through a tube attached to an orifice at the top. On being raised out of the water the jar will be found to retain its contents, the muslin mesh performing the functions of capillary tubes. At each of the meshes there is a well-marked meniscus. A Bunsen burner may now be lighted and placed beneath the water, the temperature of which may be raised even to boiling without any of its contents escaping through the meshes. It will fall, however, if the boiling is too violent.

BRICKS FROM SLAG.—The utilization of slag waste is fast assuming considerable economical importance. The manufacture of bricks from granulated blast-furnace slags will soon be begun in Germany. The slags are run into water, and the grit thus obtained is mixed up with lime, concrete or plaster of Paris, and formed into bricks, which are dried for a month. They possess greater solidity than common brick, and seem to resist a much greater pressure.

SOLVENTS FOR CAOUTCHOUC.—The best solvent for caoutchouc is said to be caoutchoucine, which is obtained by subjecting rubber to dry distillation. Other well known solvents are chloroform, carbon disulphide, resin oil, coal naphtha, rectified spirits of turpentine, tar, the oils of lavender, sassafras and rosemary, and benzine (petroleum spirit). Pure oil of turpentine dissolves 49% of caoutchouc. A mixture of 6% to 8% of absolute alcohol and 100 of carbon disulphide is said to be an excellent solvent. Sulphuric ether, which alone is a poor solvent, dissolves more readily if about 5% of absolute alcohol is added. Hot alcohol dissolves out about 4% of a soft resin. It is sparingly soluble in not fused oil; readily at a gentle heat in melted hog's lard, or in very hot whale oil. After swelling up in oil of turpentine, or in naphtha, it is soluble in hot linseed oil.

PAPER FROM A NEW SOURCE.—A new branch of industry has sprung up in Sweden lately—the fabrication of paper from moss, not from the living plant, but from the bleached and blanched remains of mosses that lived centuries ago, and of which enormous masses have accumulated in most parts of Sweden. A manufactory of paper from this material has begun operations near Jönköping, and is turning out paper in all degrees of excellence, from tissue to sheets three-quarters of an inch in thickness. These latter are harder than wood.

ALUM WATER FOR EXTINGUISHING FIRES.—M. L. B. Demas, member of the French Academy of Sciences, has discovered that water saturated with alum has superior value in extinguishing fires—a value supposed to be due to the coating it gives to objects wet with it, which prevents contact with the oxygen of the air, and thus diminishes the rapidity of the combustion. Experiments are to be made by supplying the firemen of Paris with instruments to throw it, and the Minister of the Interior has recommended that the firemen of the French communes or towns be supplied with facilities to use such solutions of alum.

ELECTRIC PATENTS.—There were 190 patents granted in Germany between May and October for inventions connected with electricity. Telephones are being adopted on a scale of increasing importance in that country, there being now—according to the statements made at a recent meeting of the Berlin Electro-technical Society—telephonic arrangements in eighteen German cities, comprising 3,785 different stations. The total length of the telegraphic lines used in the above telephone services is 540 miles, these lines comprising single wires 4,017 miles in length.

IF Javelle water be put on fruit stains in linen or other fabrics, and immediately washed out in soap-suds, the stains will be eradicated. If Javelle water is not at hand use chloride of lime, four ounces to a quart of water; shake and allow to settle, then apply to the spots, rinse in clean water thoroughly before applying soap. This precaution must be observed, or the fabric will be left harsh and stiff. Any drug store can supply you.

GOOD INK ERASER.—Lime water, with a small quantity of acetic acid, makes a good ink eraser. It should be carefully secured from exposure to retain its strength. It is usually kept in a bottle closed either with a stopper or a cork or bung of beeswax or gutta-percha. But with the utmost precaution that can be taken, it will still be necessary to make a fresh preparation from time to time.

GOOD HEALTH.

Milk and Oil in Disease.

Dr. W. W. Townsend, a well-known physician in Philadelphia, in writing to the *Scientific American* on the use of milk as a diet in dysentery and typhoid fever, says: "I am now in my 75th year, and have witnessed several epidemics of dysentery, typhoid, scarlet, and relapsing fevers, smallpox, measles, etc., and have used milk in every case coming under my care for near 40 years, in every stage of the disease. I will not say it is a cure, for I do not believe in the so-called 'cures' and 'specifics.' Milk is the natural food of all mammals. It not only sustains life, but promotes the growth of every part of the system. No other article contains all these ingredients. It is the recuperative power of nature that performs the cure; and he who studies how to assist it by sustaining the system is the best physician, and milk is one of the best agents that can be used. In dysentery I prefer fresh buttermilk, and all the patient wants is perfect rest, and discard all irritating cathartics and purgatives. Mercury in any of its preparations is poison in dysentery or scarlet fever, and the physician who gives them will never be successful. If his patient recovers it will be despite his treatment. I will add that in smallpox and scarlet fever I anoint the patient from head to feet with olive oil, by means of a badger brush, and repeat as often as it disappears, thereby allaying the heat, keeping open the pores of the skin, producing quietude, preventing congestion of the capillary circulation, and obviating the necessity of anodynes. I have practiced the greasing for 35 years, and was sneered at by my medical brethren for it and the milk treatment. Now, I believe it is in general use with the best results.

THE SIN OF FRETTING.—There is one sin which, it seems to me, is everywhere and by everybody, underestimated, and quite too much overlooked in valuations of character. It is the sin of fretting. It is as common as air, as speech so common, that unless it rises above its usual monotone we do not even observe it. Watch any ordinary coming together of people and see how many minutes it will be before somebody frets—that is, makes a more or less complaining statement of something or other which most probably everyone in the room, or on the stage, or the car, or the street corner, as it may be, knew before, and which most probably nobody can help. Why say anything about it? It is cold, it is hot, it is wet, it is dry; somebody has broken an appointment, ill-cooked a meal; stupidity or bad faith somewhere has resulted in discomfort. There are always plenty of things to fret about. It is simply astonishing how much annoyance and discomfort may be found in the course of every day's living, even at the simplest, if one only keeps a sharp eye out on that side of things. Even Holy Writ says we are born to trouble as sparks fly upward. But even to the sparks flying upward, in the blackest of smoke there is a blue sky above, and the less time they waste on the road the sooner they will reach it. Fretting is all time wasted on the road.—Helen Hunt.

A LIVE SNAKE IN A HUMAN STOMACH.—The following item, with slight alterations, is taken from the *Oakland Tribune* of recent date: The reprint is only after a personal interview with Mr. Wright, who assures us it is strictly correct. We have known the gentleman for many years, and believe him to be perfectly reliable. "Mr. Alfred Wright, a mining expert, who resides on Eagle avenue, between Park and Everett, Alameda, and who has, of late, been giving his attention to the raising of fruit trees, has been singularly ill for two years past. He was troubled with strange movements in his stomach, and afflicted with an inordinate appetite. He tried various physicians without obtaining relief, most of them pronouncing his malady dyspepsia. He finally went to treating himself. Recently he has had fears in reference to some living thing within him, and abstained as far as possible from food. He then took some herbs, which actually killed whatever it was. During the past two weeks he was relieved of a brown snake three or four feet long. A portion of the skin, by actual measurement, was fifteen inches in length and one inch in diameter. His impression is that he swallowed it while drinking water from a stream in the mountains. This is one of the most remarkable cases on record. Mr. Wright is doing well."

RESPIRATION AFFECTED BY FOOD.—A very careful examination by Dr. Speck of the changes produced in the respiratory process by the use of fatty food, of coffee, quinine, alcohol and water, and by the inspiration of air respectively rich in carbonic acid, poor in oxygen and rich in oxygen, has led him to the following conclusions: With an increased proportion of hydrogen in diet, the amount of air inspired and expired decreases, and nutriment, such as sugar, which contains little hydrogen in comparison with their oxygen, involves more exertion of the respiratory organs than such as are rich in hydrogen like the fats; the more carbon predominates in the food in proportion to hydrogen, the more air is exhaled in proportion to that inhaled; the more carbon increases in the diet in proportion to hydrogen, the more carbonic acid is evolved and the more oxygen is taken up—while the richer the diet in hydrogen the less oxygen is required. An atmosphere containing five per cent, or six per cent, of carbonic acid could be breathed for some minutes without oppression; at 11.51% great exertion would be needed to breathe for one minute; at 7.2 all carbonic acid produced in the body is retained in the blood.

SMOKING BOYS.—A medical man, struck with the large number of boys under 15 years of age he observed smoking, was led to inquire into the effect the habit had upon the general health. He took for his purpose 33, aged from nine to fifteen, and carefully examined them. In 27 he discovered injurious traces of the habit; in 22 there were various disorders of the circulation and digestion, palpitation of the heart, and a more or less taste for strong drink. In 12 there were frequent bleedings of the nose, 10 had disturbed sleep, and 12 had slight ulceration of the mucous membrane of the mouth, which disappeared on ceasing the use of tobacco for some days.

CONSUMPTION.—Koch's discovery of the true nature of tubercular consumption has naturally raised the hope that some means may be found to destroy in the system the organisms producing the disease. Mons. De Korah has recently described to the Paris Academy of Sciences an interesting experiment bearing on the subject. Tubercular matter from a guinea pig was placed in 10 tubes under favorable conditions for development. Into three of the tubes helenine was introduced. At the end of a week the matter acted upon by the helenine had lost its infective power, while that in the other tubes still readily produced tuberculous.

BLACK CORN, it is said, has been raised in Livingston county, N. Y. It is described as being as black as an African, as sweet as sugar, and retains all these attributes when cooked.

 Mechanical Engineer—W. W. Bailey, S. F.

Passing Events.

This week the Legislature has convened at the State capital. The retiring and incoming Governors have sent in their messages, and the work of making laws has been commenced. We shall during the session keep track of all that is of interest to the mining or manufacturing community.

The deliberations of Congress on the tariff question are being carefully watched by those interested in several branches of the mining industry. Some changes are contemplated which will be detrimental to those interests.

From the various States and Territories where precious metal mining is carried on, come tidings which show an increased yield for the past year. We shall shortly issue our annual mining review, which will give a summary of the year's progress in all quarters.

A DISPATCH from Virginia City states that the honanza folks are having abstracts of the titles of all the mines, from Potosi to Belcher, made. Five men are at the job, which will take nearly a month. This is supposed in Virginia City to mean a movement in the flooded mines under one management.

THE Wood River Times reports hundreds of certificates of new locations poured in on the Recorder of that district on the two first days of January, indicating that much jumping of claims must have taken place.

Foundry Notes.

Most of the foundries of this city are pretty busy just now, considering the season of the year. The main work is mining machinery, but a great deal of other work is being done also. Perhaps the heaviest piece of work, aside from the mining machinery now being made, is that of the second dredger for the Panama canal, which is now nearing completion at the Golden State and Miners' Iron Works. This second machine is the same size as the first one which was made by these works and shipped East. The big scow on which the machinery is to be placed was launched the other day at Port Richmond, Philadelphia. The machinery is all to be placed in position and tried somewhere there, and then the upper part will be taken down and stowed in the hold, and the scow towed to Panama. The new machinery now being built here will be shipped East and put on another scow, which will then be towed to Panama. A third one is to follow, work being already commenced on it here.

There are about 300 tons of iron in the machinery of each one of these dredgers. The dredge is a bucket one with endless chain. There are about 40 buckets, and 16 of these a minute discharge into a large pipe at the top of the machine, the mud passing through this pipe to the bank or levee which the machine is to form. Where there is sand a hydraulic nozzle is used to wash the sand out of the buckets in case it shows a tendency to stick; but this is not necessary in digging mud. The main driving engines are each 100-horse power, and they are made in a most substantial and plain manner. There are also three other pairs of engines, of 20-horse power each, for raising and lowering the buckets, handling the spud, etc. Steam is used for all purposes, and one man can control all the mechanism. In fact, only five men altogether are necessary to run the machine. The scow on which the machinery is placed is 100 feet long and 60 feet wide. The whole dredge cost about \$150,000. The machine is on the plan of that which has been doing such effective work on the tule lands of this State, under the supervision of General Williams. The work accomplished has been so remarkable that a great many Eastern people have come here especially to see it work. The engineer of the Panama canal was one of these, and Col. Totten, U. S. A., also reported on it. The first machine had a stump-pulling apparatus, which the others have not.

In addition to this work this foundry has just sent away a 10-stamp mill to Mexico. The mill was all made in sections for convenience in packing on mule back. All the pans, settlers, etc., were made in the same way. A 10 stamp silver mill has been made for Silver district, Arizona, just above Castle Dome. Pans, settlers, rock breaker and the usual things go with this mill.

They are also making a Wheeler rock breaker for Globe district, Arizona, and doing considerable bridge work for Mexico. They are making a good deal of iron work for Carter Bros., of Newark, Alameda county, who are doing an immense business in building cars for narrow gauge railroads. The foundry has just sent off a lot of hydraulic elevators for Portland, Oregon. They are making quite a number of Milliken's hydraulic ram elevators, which are taking first rate. A great many of this style of elevators are being introduced, as they are seen to be perfectly safe from accident, and are durable and strong. In many new buildings this form of elevator is taking precedence. It has been put in most of the new large buildings recently put up, as Phelan's block, Fair's building, and at Huntington, Hopkins & Co.'s and many other places.

The Golden State and Miners are building two rock crushers or pulverizers of E. Chiquette's patent. There are a few of these machines running here, and one of these being built is for a man who has been using one for some time.

MACHINERY AT THE DENVER EXPOSITION.

In our special notice of "Machinery at the Denver Exposition" we inadvertently omitted to make allusion to the really fine and large exhibit made by Messrs. Fraser & Chalmers, of Chicago. The motive power by which nearly all the machinery in the building was driven was an improved 24x28 Corliss automatic out-off engine, with two 60-inch boilers, each 16 ft. long, with a Baragwanath improved. The engine was rated at 250 horse power, and was employed to drive a 25 inch belt with a 16 ft. wheel. In addition, they also exhibited a Comet quartz crusher, a double Huntington quartz mill, an improved Frue vanner, and an assortment of other smaller machinery. They also exhibited a 30-horse-power engine for driving dynamo machines, with 25 electric lights, embracing two 10-light and one 5-light Weston machines with 25 lamps. Their exhibit, taken altogether, was one of the best and most extensive single displays in the building. Messrs. Fraser & Chalmers have their general office at Chicago, with branch offices in New York, Butte City, Montana, and Denver, Colorado.

ASBESTOS gloves are made and sold in considerable quantities by the H. W. Johns Manufacturing Co., of New York.

California Quicksilver.

The Industry and the Tariff.

The production of quicksilver is one of the most important interests of the Pacific coast, representing a capital of \$30,000,000, and giving permanent employment to more than 5,000 men, who are paid liberal wages. For many years, while the article was protected by a duty, the business was profitable to the producers, and some 30 mines were in operation in the State. Within the last few years, since quicksilver was placed on the free list, and owing to competition with foreign producers, particularly of the Almaden mines in Spain, which are owned and worked by the Spanish Government, and the Idria mine in Austria, worked by the Austrian Government, the price has been reduced to so low a figure that the California quicksilver miners say there is no profit to them in the business.

Eight mines only are now being worked in California, as follows: Quicksilver Mining Company, New Almaden, J. B. Randol, manager; Sulphur Bank, Parrott & Co., agents; Great Western, P. Palache, President; Redington, John F. Redington, President; New Idria, Thomas Bell, President; Santa Clara Mining Association, of Baltimore (the Guadalupe), Henry May, receiver; Oakland, Thomas Bell, trustee; Napa Consolidated Mining Company. It is represented that the total amount received for sales of this article during the last three years has not paid the cost of production, allowing for depreciation in works and exhaustion of the mines. Owing to the richness of the Spanish and Austrian mines, and the fact that the cost of labor in those countries is not more than one-sixth of what is paid in California, quicksilver cannot be produced in America to compete with the product from Spain and Austria, and unless some relief and protection is given, this important interest must give way to foreign competition.

Owing to the high rate of transportation between California and the Eastern States, foreign quicksilver can be sent from Europe to New York at one quarter the freight and in one-third of the time that it can be sent from San Francisco. The freight from here to New York is two cents per pound, or \$40 per ton. From London to New York freight is \$12 per ton, and it takes 10 days from London and 21 days from here. The mines here cannot therefore sell their product in New York. Last year London sent to New York 12,000 flasks—1,000 flasks a month, but shipments East from here must cease under such conditions.

Many articles necessary for the working of quicksilver mines, particularly iron, steel, coal, etc., are subject to high duties, thereby largely increasing the cost of production. Empty quicksilver flasks are subject to a duty of 35%; that many of the flasks used in California are flasks of American make returned from foreign countries, on which the quicksilver manufacturers here are obliged to pay the high duty, often many times on the same flasks, while foreign flasks filled with foreign quicksilver are imported into the United States free of duty! Owing to these facts, all of the American market east of the Rocky Mountains has been lost to California manufacturers, and supplied with a foreign product which pays no duty nor revenue in any way to our Government; but, on the contrary, is protected and favored over the American product to the extent of 35% duty, paid by the American mines on empty flasks, which are classed under the head of manufactured iron.

The imposition of a duty on quicksilver would lead to no hardship or damage to other industries in this country, the article being used over many times in gold and silver mining, so that the small advance in price would practically be almost nothing in the cost of mining, while the only other industries which would be affected—the manufacture of vermilion and the manufacture of medicinal preparations from mercury, both of which are small in comparison with the manufacture of quicksilver—are now protected by a duty.

Owing to the great extent and richness of the Spanish mines, as compared with any mines in this country, and the low rate of labor in Spain, the Spanish Government can at any time produce quicksilver in sufficient quantities to supply the consumption of the world, and at a price which would close every mine in this country. The control of this Spanish product is a practical monopoly in the hands of Messrs. Rothchild, of London, who have the control of the Spanish mines production for 30 years to secure the payment of a loan to that Government. There is a very large accumulation—more than 100,000 flasks—from the products of these mines now in London.

Prior to the manufacture of quicksilver in California the price of foreign quicksilver was more than treble the present price, and, should the California mines, which are practically the only competitors of the Spanish and Austrian Governments' mines, be, for want of protection, driven from the field, the price of the foreign article would be advanced to a rate that would compel the consumers of quicksilver in this country to pay a hundredfold more than the imposition of a duty on the American product would cost them, and practically subject the mining of gold and silver in America, for which quicksilver is indispensable, and the price of bullion to the control of foreign governments.

product of quicksilver. In 1874 the price in London was advanced to one dollar and seventy-five cents per pound. It is now selling in San Francisco at 34½ cents per pound. The admission free of duty of the only product manufactured exclusively by foreign governments (which themselves have a high protective tariff), to the detriment and ruin of an American industry, is an anomaly in our revenue laws which the quicksilver miners want to see at once removed.

Careful estimates recently made from the different mines show that for every flask of quicksilver manufactured, nine days' actual labor is used, which, at the low average of two dollars per day, would make the amount paid to workmen \$18 for every flask manufactured. It is now selling for less than \$26 per flask, and the amount over what is paid for actual labor will not pay the cost of fuel, powder, flasks, steel and other materials protected by duties and necessarily used in the mining of cinnabar ore and its reduction to quicksilver. It seems almost a self-evident proposition that if any article of American manufacture is protected, quicksilver should share in such protection.

All other metals of American manufacture, from native ores, iron, copper, zinc, nickel, lead, etc., are protected by high duties; quicksilver, which under the present foreign government competition seems to require it more than any other, forming the only exception. The business is subject to all the extraordinary risks and uncertainties of mining, with the added costs and difficulties of converting the ore into quicksilver and finding a commercial outlet for it.

Contrary to the general supposition, there is no tariff on quicksilver, though the daily papers have been publishing dispatches saying the duty was about to be removed. It has been free of duty since 1874. Under the old tariff the duty was 15 per cent. *ad valorem*, and ranged in amount from 10 to 25 cents per pound. All these facts have been presented to Congress in a memorial from the quicksilver miners of California, who ask to have a specific duty of from 15 to 20 cents per pound imposed, 15 cents being, in their opinion, the lowest figure which may enable American manufacturers to compete with the Spanish and Austrian Governments and give a fair return for capital invested.

In conversation with the manager of the most extensive mines in California, the writer was told that unless some such duty was imposed, in three years there would not be a quicksilver mine at work in this State. In fact, several will close down this year unless the duty is put on the metal. California is particularly interested in this matter, as she is the only producer of quicksilver in the United States. General Rosecrans, the Representative to Congress from this district, has actively interested himself in the subject, and by persistent and intelligent work, is bringing the matter before Congress in such a way that there are strong hopes among the quicksilver miners—thanks to his help—of carrying the point.

CASKS OF STEEL.—An English firm has recently turned their attention to the manufacture of casks and barrels of steel. The two edges of the sheet of steel which form the cask are brazed together in such a manner as to justify the title of "seamless," which the patentees have applied to those productions. The head of the barrel is also riveted to the body, so as to leave no seam, and the end rims are shrunk on hot, thus making a very solid end, whilst, at the same time, the rims are thick enough to give a good purchase to the grapples of hoists and cranes for loading and unloading purposes. The hush for this tap does not project beyond the rim, so that the nozzle is not liable to be knocked about and injured. The casks are more durable than wood, less bulky, and it is said lighter—an eighteen-gallon steel cask weighing some ten pounds less—a not inconsiderable consideration as regards transit. In point of shape the steel barrel is exactly that of a well-formed wood one.

THE Evening Star mine, which has been the pride of Leadville, has ceased producing. The mine has paid dividends to the amount of \$1,500,000, and its gross product has amounted to something like \$3,000,000. The Leadville Chronicle, in speaking of the mine, says: "We must not be understood as intimating that the Evening Star is exhausted, but simply that the managers see themselves near enough to the end of the resources to incline them to direct their attention chiefly to the work of exploration."

A COMBINATION OF ASBESTOS AND INDIA RUBBER has been very successfully introduced in its application to valves of large size for steam by Mr. B. Rhodes, of London. The advantage of the material consists in its great durability under steam, as the heat does not affect the asbestos, and new settings can be readily applied without breaking any joints or removing the body of the valve, a point of great consideration where a large mill is depending on the steam valve for motive power.

SELLING PATENTS.—George B. Davis, the well-known agent for the sale of patents in the United States and Europe, has moved his office from 503 California street to room 14 over Wells, Fargo & Co.'s bank, corner California and Sansome, as will be seen by our advertising columns.

Notes From Eureka, Nevada.

[From our Regular Correspondent.]

The actions of the accumulator for the Eureka Con. new machinery are at hand, and Mr. Moore, from the Edison Iron Works, at San Francisco, is here to superintend the erection of them. When all is ready, the sinking of the high shaft will be resumed, and in a few months we shall know a little about what there is below the 12th level.

What is going on at the Richmond mine it is difficult to tell, and can only be guessed at. At the last bi-yearly meeting of the stockholders in London, Eng., it was shown that the company, during the past six months, have realized a net profit of £30,000—or nearly \$150,000. A letter from Mr. Probert, the manager of the company at Eureka, was read at the meeting, showing that there is still a vast amount of unprospected territory in the Richmond mine; it also states the gentleman's views in respect to the future of the property, which are decidedly favorable. At the Richmond reduction works there are now

Two Forty-Ton Furnaces Running.

One of them was started up this morning, and is working splendidly. The smelters and helpers say that no furnace ever built in this district has made such a clean start. It was built under Mr. Probert's direction and according to his own plans. This afternoon I went to

The Albion Mine,

And under guidance of Mr. John Williams, the foreman, got in the cave and was lowered down to the main level, through which we passed to the junction and thence southeast to the foot of a ladder on which we climbed through an uprise to the foot of an incline leading up to the Mammoth cave. From there we continued going upwards until the top of the cave was reached, and then sat down to catch our breath now nearly exhausted. From the top of the cave we again commenced climbing, and reached the June drift 75 ft. above it. This brought us to the June chamber, which I can but imperfectly describe. We rested on floor A, below which are three other floors, X, Y and Z. Above it are six floors, B, C, D, E, F, G, making in all 10 floors. These are laid on massive square sets of timbers six feet high, six feet long and five feet wide from centers to centers. Where the square sets are now there was originally ore, but at present most of the space has been filled in with waste rock and earth, leaving a walled up passage through it to admit of ingress and egress. From floor A we descended through the June winze to the November level, and then proceeded to the November cave. Here we found but one man at work. He was prospecting, and had just struck a bunch of ore, fine looking and giving indications of making into a body. From this point we passed up through another portion of the June chamber to the X, Y and Z floors. By the marks on each post we could tell precisely what part of the chamber we were in, and by the same marks I noticed that the chamber was 45 ft. wide and 85 ft. long on these floors. It is also 60 ft. from top to bottom as far as explored; but as there is still a plenty of ore in sight, there is no telling where it will end. We next retraced our steps and went through the November drift to a chute into which the ore from the June cave is dumped and conveyed to the main level. Mr. Williams now placed me in charge of a miner, and went to look after his men. My next point was the east raise, to reach which we had to go back to the Mammoth cave. Again we started from this point, and, going directly to the east raise, found that a large amount of ore had been removed since my last visit, and all the way up the raise there is from three to eight or ten feet of ore, making, in a northerly direction, as I judge (not having a compass with me, I had to rely on my judgment as regards direction, and may be somewhat at fault in regard to it). Upward we went a great distance, keeping the ore at our left hand all the way up and dipping away from us. This, I think, is the December cave, but I am only guessing, as my present guide could tell me nothing. We again retraced our steps to the October drift, and thence found our way to the October cave. Here were

Miners Taking Out Ore

In the same manner as laborers would take sand from a sandbank; no timbering, but working up against a bank of ore over 20 ft. high at the breast. By means of a ladder we climbed up over this, and, going through a natural hole in

lime rock, reached the January cave, where the ore is making strong towards the surface. The Albion is certainly a big mine, and, considering the immense amount of territory that it covers, it is reasonable to suppose that it cannot be worked out for a great number of years. The amount of exploration work done and the manner of its performance speaks volumes for E. N. Robinson, the superintendent. The development of a mine is by no means "baby work." It requires brain, engineering skill, labor, energy, perseverance and a large amount of money. Of all these Eureka district is much in need. Did she possess them we could show to the world the highest mining camp upon the face of the globe.

I hear that the Bald Eagle and Pioneer mines, now in litigation, are to be consolidated.

A Suggested Consolidation.

I would respectfully suggest that these, the Danderberg series, Connolly, "California and Silver King, and the Golden Rule" series (the last named contains 60 acres of good mineral ground), should all be consolidated into one or two good strong companies, such, for instance, as the Richmond Con. or Eureka Con., with ample means to develop the ground embraced in the several claims. There is no doubt that in various portions of these claims vast deposits of ore exist, no matter what may be said by persons peculiarly interested in making it appear to the contrary. I will now call attention of the readers of the MINING AND SCIENTIFIC PRESS

To Adams Hill

At the Horne Tony work on the shaft has been

Horse Power of Water Wheels.

In the accompanying table, which is designed to show graphically the horse power of water wheels, the lines of horse power are parallel and equidistant. The lines of heads in feet are parallel and are set at distances from 0 proportional to the cube of the square root of the head in feet. The lines of diameters are drawn diagonally, and intersect the lines of heads in feet proportionally to the squares of the diameters.

In order that the diagonal lines should not be too crowded, those representing diameters from 5 inches up to 24 inches have been drawn from one corner, while those from 25 inches up to 72 inches have been drawn from the adjacent corner on the line of 0 feet head. The lines of horse power are numbered increasing from the origin of the lines of diameters which they are designed to measure.

To illustrate the method of using this scale, take two examples. First, a 30-inch wheel under 70 feet head. Following the line marked 70 in the margin of "Heads in feet for large wheels," to its intersection with the diagonal of 30 in. diameter and then going back from the opposite side of the diagonal in the line of horse power, the figure in the margin will indicate 200 horse power.

Second, a wheel of 15 inches diameter under 300 feet head. Taking the line marked 300 in the margin "Heads in feet for small wheels," to its intersection with the diagonal of 15 in.

Mining Expositions.

In his message to the Legislature of this State Governor Perkins speaks as follows of the recent mining exposition at Denver, Colorado: In the month of June last I received from Governor Pitkin, of Colorado, an invitation from the Directors of the National Mining Exposition, to be held at Denver in the months of August and September, requesting me to appoint a commissioner to represent this State therein. Believing such representation would be advantageous to our people, and be the means of advancing its commercial as well as its mineral interests, I urged on Warren B. Ewer, Esq., of San Francisco, the acceptance of such appointment. His commission as such agent was forwarded him, and in accordance therewith he proceeded to discharge the duties required of him. His report, which accompanies this message, is the strongest evidence of the wisdom of the appointment, and further shows the necessity of the State's encouraging such expositions; the meager exhibition of the mineral and metallic production of California does not speak very favorably of the business qualifications and energy which is the boast of a Californian.

I commend the report as full of suggestions, many of which, if adopted, would bring the State more prominently before the commercial and scientific men of the world, as well as to those who are seeking to create homes, thus advancing the Commonwealth in all its varied interests.

I respectfully call your attention to the fact that no appropriation was at my command to pay any of the expenses incurred by Mr. Ewer, and he was so informed, with the understanding, however, that I would refer the matter of compensation to you. I therefore ask that the Legislature pay the same, being the trifling sum of \$121.

An appropriation of \$5,000 was made at the last session to provide for a proper representation of California at the World's Exhibition, to be held in New York in 1883. None of this money has been used, the exhibition having been postponed, hence the small sum recommended above may well be granted.

I have been officially notified by James De Fremery, Esq., Consul of the Netherlands, of the intention of his Government to hold an International Exhibition at Amsterdam during the present year, and inviting the participation.

of this State therein. Great efforts are being made to insure its success. This exhibition offers a rare opportunity to bring to notice the resources and advantages of California. The leading countries of Europe have already taken measures to have their several industries represented therein. The great usefulness of these international exhibitions has so frequently been demonstrated that it seems unnecessary to call special attention to them.

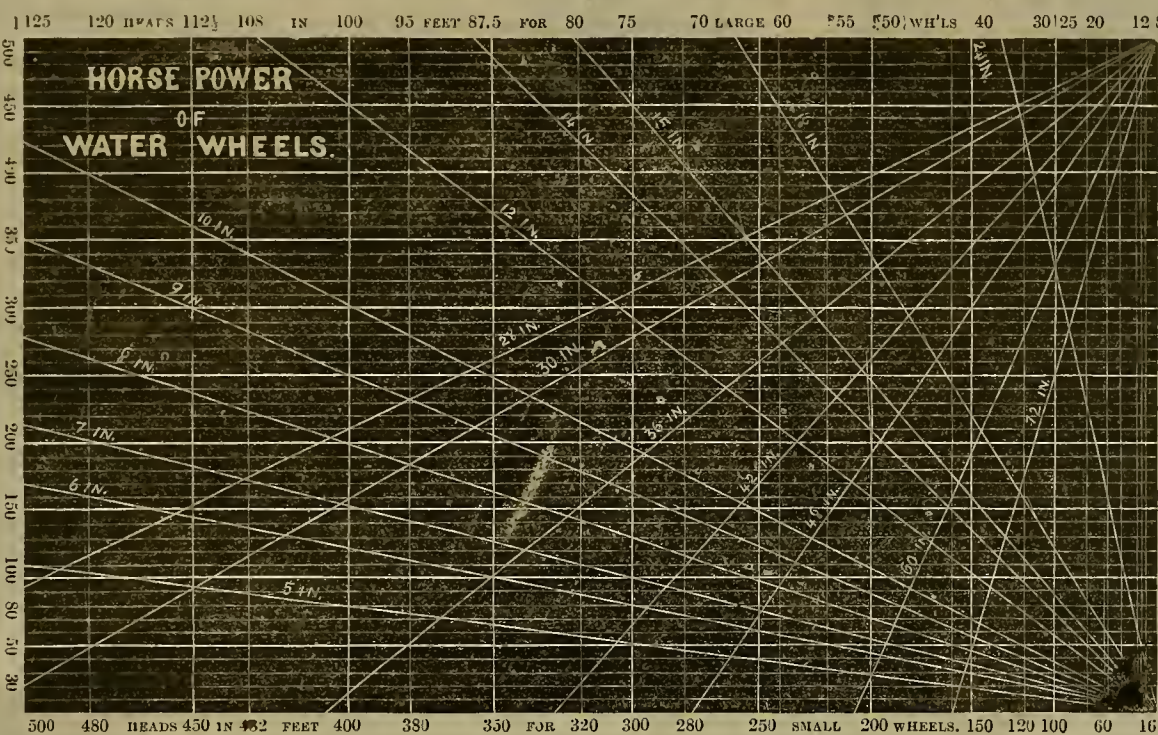

The State should avail itself of this opportunity to impress the advantages for settlement, for agricultural and industrial pursuits, etc., upon the multitudes that will visit this exhibition, and who will carry their acquired knowledge and impressions to every nook and corner of Europe.

I have been informed that articles representing the resources of California, with specimens of her minerals, would be donated for this purpose if the expenses incident to their care and transportation were provided by the State.

A FEW years ago copper leads in Montana were given the go-by by prospectors as valueless. Nothing but gold and silver prospects were considered worth the trouble of locating and recording. To-day copper is the most valuable product, and the rich copper mines of Montana are attracting fully as much attention abroad as her silver bonanzas.

LOCATING AT MIDNIGHT.—At Omo there was a crowd on hand New Year's for the purpose of relocating jumpable claims. Many were up till after midnight—till Monday morning was fairly ushered in—waiting about bonfires (which they had built in various places in the hills) for the moment to arrive when they could legally post their notices.

THOMAS DONOVAN was killed in the Huhn & Hunt mine, Nevada, by a cave last week. He landed in California in early days and he worked in the mines and mills of the Comstock for several years.

quit for the present to prospect for a "grub stake," the parties leasing and taking out flux, of which there is a great deal. There is also three or four tons of high grade ore on the dump.

At the Rio Members the main shaft is down fifty feet, and a cross cut has been driven forty feet on solid hard quartz that will work about \$15 per ton, which as soon as hoisted to the surface is bought by the Albion Company at \$2 per ton, and by them hauled to their furnaces to be used as flux for their own ores. Through the quartz are veins of carbonate ore running from \$90 up to \$165 per ton.

At the Silver Lick series a new double compartment shaft is being sunk, from which at a depth of 50 ft. from the surface a drift is being run to strike the lode. The extreme east end of the series is leased to parties who have been sinking out some good quartz, but have quit that for the purpose of sinking on the ledge to where they believe they will strike it higher than near to the surface. Molino and Frazier have over 100 sacks of fine rich ore on the dump, and are still going for more of the same kind. From the Herculean is being shipped for flux to the Albion eight tons of quartz per day. At Eureka No. 2 are indications around and about the shaft of a mine. There is quartz beside the dump, but as the windlass drum had been removed from the standards, and there was no person to let me down into the shaft, I cannot say whether the quartz was taken out of it or carted there from some other place. On Prospect mountain there is considerable activity, but during the past week I have had but little chance to take notes on that way. One of the important enterprises in that portion of the district is the Monumental tunnel, now in about 350 ft. in hard lime rock, which the contractors say is changing to softer ground. In fact they think they are in the casing of the ledge; but of this more anon.

M. H. JOSEPH.

Eureka, Nevada, Jan. 8, 1883.

The Miners' Association, which is making the debris fight, has issued a call for more money.

diameter, and following the "horse power" line from the same side of the diameter line to the margin it will be found to indicate 450 horse power.

The diagram is drawn upon a basis of useful effect of 80 per cent. of the theoretical power of water, and a full gate opening having a fixed proportion in square inches to the diameter of the wheel in lineal inches. This is one of the diagrams accompanying the drawing of Schussler & Eckart's water wheel, in the circular of the Union Iron Works of this city.

LARGE PEARLS.—The Pacific, of Mazatlan (Mexico), has the following: The largest pearl in the world has been found recently in Lower California (Mexico) by one of the fishers (or divers) belonging to the firm of Gotzalk and Ruffo, merchants at La Paz (L. C.). The pearl is of the dimension of a lemon, weighing 75 carats and measures one inch in length and three-fourths of an inch in width. It took the fisher who opened the shell several minutes to extract the pearl. There is no doubt that the coast of Lower California is very rich. The largest pearl known before was also found on that coast, in Loreto (L. C.), in the time of the Jesuits, and adorned the crown of the Queen of Spain.

JAMES BROWN, chief engineer of the Ourario mine, Park City, Utah, died in Salt Lake City on the 22d of last month. Deceased was 49 years of age, and a native of Preston, England. He was formerly foreman of the Gold Hill foundry, and subsequently held the position of chief engineer of the Ophir mine.

BULLION OUTPUT OF LEADVILLE.—The bullion product of Leadville district the last quarter was as follows: Pounds lead, 17,009,228; ounces silver, 1,336,112; ounce gold, 2,921. Total currency value, \$5,783,127. Total value of output for the last four years is as follows: 1879, \$10,333,740; 1880, \$14,187,697; 1881, \$13,170,567; 1882, \$18,220,893.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars. Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 30x36. BOILERS of every form, made of Plain Iron Works C. H. No. 1 Flange Iron, or Otto Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

THE ROLLER ORE FEEDER.

Patented May 23, 1882.

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required. In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

Golden State and Miners' Iron Works, Sole Manufacturers, 237 First Street, SAN FRANCISCO, CAL.

FACTORY BUILDINGS

AND.

MACHINERY

Located on the Shore of San Francisco Bay.

For particulars apply to C. G. Yale, 414 Clay Street, San Francisco.

To parties contemplating the erection of new works for manufacturing purposes this is

A BARGAIN.

The plant will be sold at a very low rate.

CHAS. E. LLOYD.

J. S. BEARDSLEY.

BEARDSLEY & LLOYD,

REAL ESTATE AGENTS.

No. 912 Broadway Street,

Between 8th & 9th Sts., Oakland.

Particular Attention given to Negotiating Loans upon Favorable Terms. Acting as Agents for Buyers and Sellers of Real Estate, and the Management of Business for Absent Owners.

JOHN BERGSTROM,

ORGAN BUILDER.

9th. and Mission Sts.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER.

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Dewey & Co., { 252 Market St. } Patent Agt's

JAMES LEFFEL'S WATER WHEEL,

The "Old Reliable,"

With Important Improvements, making it the

MOST PERFECT TURBINE NOW IN USE,

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those owning water power. Those improving water power should not fail to write us for New Prices, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO.,

Springfield, Ohio, and 110 Liberty Street, New York City.

PARKE & LACY, General Agents, 21 & 23 Fremont St., S. F.

THE MOREY & SPERRY MINING MACHINERY CO.,

Successors to MOREY & SPERRY,

Manufacturers of all kinds of

MINING MACHINERY.

Gold and Silver Grinding, Concentrating and Amalgamating Machinery, Engines and Boilers of any size. Hydraulic Giants, Hydraulic Outfits. All the various kinds of Amalgamating Pans, Combination, Edipse, Excelsior, etc. Settlers, Rock Breakers. Stamp Mills for Wet or Dry Crushing. Howland's Pulverizer, Improved Riffles, Retorts for Gold and Silver, Silver Plated Copper for free Gold Amalgamation. Hoisting and Pumping Machinery, Chloridizing Furnaces, etc. Mining and Mill Supplies of every description. Steel Shovel and Dies that last three times as long as any iron.

WAREHOUSES: 92 & 94 Liberty St., New York,

Foundry and Machine Shop: Newburg, N. Y.

NOTICE.—The public and former friends and patrons of the old firm of Morey & Sperry are hereby notified that the above-named Company is the legitimate and ONLY successor to the said firm, having acquired all the drawings, patterns and machinery of the old firm, together with the lease and good will of its business.

We shall continue the business, with largely increased facilities, at the old place, having made connection with the Morey, of the late firm of Morey & Sperry, will manage the business of this Company. Information and estimates of the various styles of Mining and Milling Machinery cheerfully given. All orders filled promptly. Materials and Workmanship First-Class.

MOREY & SPERRY MINING MACHINE CO.

DEWEY & CO.'S

Scientific Press

Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

A. T. DEWEY.

W. B. EWER.

GEO. H. STRONG.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS

All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

- NO. 1.—The most Powerful Explosive Compound now in use here.
- NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
- NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much faster. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro-Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same.

BANDMANN, NIELSEN & CO., General Agents, 210 Front St., S. F.

Redlands.

Good water, rich soil and magnificent view. High elevation, dry air, few fogs and northers.

No brush or fences on the land, which is especially adapted to the culture of the orange and raisin grape.

Near to church, school, store and depot. Hotel open. Telephone Communication.

Stage from San Bernardino Tuesdays, Thursdays and Saturdays.

SEND FOR CIRCULAR.

JUDSON & BROWN,

Redlands,

SAN BERNARDINO, CALIFORNIA.

The "Orland" Patent SEWER GAS TRAP

Is a sure shut-off against Sewer Gas and Back Water. The Loaded Metal Ball Valve is slightly heavier than water. This Trap can be put in at small expense, and is warranted to give satisfaction. Highly recommended by leading Architects and Plumbers. Used in all new, first-class buildings in San Francisco, including the Plaza Hotel. For sale by all dealers in Plumbers' Goods, and by the "GALAND" IMPROVED SEWER GAS TRAP MFG CO., 1901 Broadway, Oakland, Cal. Coast Rights for sale.

BOONE & MILLER,

Attorneys & Counsellors-at-Law,

Rooms 7, 8 and 9.

No. 320 California Street, S. F.,

PATENTS AND INVENTIONS

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in Dewey & Co.'s Scientific Press Patent Agency, 252, Market St., S. F.

- For Week Ending January 2, 1883.
- 270,171.—CAR COUPLING.—Wm Adams, Salem, Or.
 - 269,949.—CAR COUPLING.—Geo. W. Bedbury, Portland, Oregon.
 - 269,912.—FAUCET.—J. L. Berry & S. Gladney, Antelope, Cal.
 - 270,001.—CRAIN SEPARATOR.—Daniel Best, Albany, Or.
 - 270,007.—EQUILIBRATING APPARATUS FOR PUMPING AND OTHER MACHINERY.—Chas Bridges, San Fernando, Cal.
 - 270,008.—LADDER.—Chas Bridges, San Fernando, Cal.
 - 269,852.—FRUIT STONER.—J. M. Harlow, Brighton, Cal.
 - 269,855.—SAFETY APPLIANCE FOR ELEVATORS.—L. H. Heydemann, S. F.
 - 269,863.—IRON AND ILLUMINATING STAIRS.—P. H. Jackson, S. F.
 - 269,948.—FEATHERING PADDLE WHEEL.—Chas. Megow, S. F.
 - 269,952.—HAND ROCK DRILL.—E. Moreau, S. F.
 - 270,009.—CORK EXTRACTOR.—Robt. Morgau, Stockton, Cal.
 - 269,903.—HAND OR WIRE VISE.—S. B. Whitehead, S. F.
 - 269,982.—TWO-WHEELED VEHICLE.—O. A. Wright, L. H. Fowler and S. Shaw, Napa, Cal.
 - 269,983.—STOCK CAR.—A. V. Anderson, Virginia City, Nev.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of special mention:

DEVICE FOR BREAKING BALKY HORSES.—Joseph Lucas, Los Angeles, Cal. No. 269,539, December 26, 1882. This invention relates to a device for breaking or overcoming the fault of horses which refuse to move at times, commonly known as "balky horses." It consists in the employment of two hoots or inclosing pieces of leather, which are fitted around the front legs of the animal just behind the knees, and have a cord or strap attached to them from the front and passing through a pulley, which is fixed to the front end of the pole, so that when the animal moves properly and freely the strap runs freely back and forth through the pulley with the reciprocal action of the front legs. If, however, the animal refuses to travel, the other animal of the team will start the wagon, and the consequent pull upon the hoots will force the unwilling animal to start.

WATCH REGULATOR.—Julius C. Landmann, Dutch Flat, California. No. 269,538, December 26, 1882. This invention relates to an attachment for regulating the speed of watches, and it consists of a segment rack attached to the outer end of the regulating arm. With this meshes a pinion, the shaft of which extends through the watch and has another pinion upon the opposite end, which is engaged by the teeth of a gear wheel, the shaft of which extends through the face and has an index-arm secured to it. By moving this index-arm the regulator is adjusted without opening the watch, a circular scale showing the amount of adjustment made.

The Garland Sewer Gas Trap.

The Garland improved sewer gas trap for wash-basins, sinks, bath-tubs, seems to be a sure seal against sewer gas and back water. With or without vent pipes, danger from siphonage and evaporation is avoided. A loaded metal ball valve, slightly heavier than water, is ground into its seat, resting two and a half inches under the water or exit pipe. This valve floats up and around the large chamber while the water is running out, and after the flow falls gently into its seat. There is a trap screw at the bottom which is easily removed for cleansing or recovering anything of value that might drop through a basin or sink. The Garland trap received the first premium at Mechanics' and State Fairs. It has been endorsed by the Oakland Board of Health. There is no department of invention that has been put to stronger tests than that of plumbing, to keep out sewer gas. The inception of many of our worst diseases is due to the escape of sewer gas through our dwellings. The Garland trap is recommended highly by J. P. Gaynor, Aug. Laver, P. Huernie, John Marquis, Wolfe & Son and other leading architects. It has been put in most of the new buildings of late, such as Phelan Block, Union Square Hotel, Page, Westerfield & Co.'s building, etc. The old-style traps have been taken out and these put in A. J. Ralston's house, Arcade house, Post Office block, Galindo hotel and Central block, Oakland. In that city also the traps are used in the houses of G. W. Mannel, S. J. Harvey, C. W. Crane, C. J. Forest, F. S. Page and others. S. H. Seymour, of the Russ house, also uses them. They are in Holbrook & Merrill's big building, are used by W. W. Montague, and among leading plumbers by Thomas Day and others. These references are enough to show the favor in which the trap is held, as will be seen by our advertising columns. The Garland Sewer Gas Trap Manufacturing Co., of Oakland are makers.

DEBILITATED persons and sufferers from wasting diseases, such as consumption, scrofula, kidney affections, will be greatly benefited by using Brown's Iron Bitters.

ASSESSMENTS falling delinquent on mining stocks in January amount to \$810,070, levied by 20 mines, against \$462,400 in January, 1882, and \$780,500 in 1881. Of this month's assessments Nevada mines call for \$285,800, California \$514,270, and Arizona \$10,000.

The Horn Silver mine of Utah produced over \$3,000,000 last year, and paid \$1,200,000 in dividends.

The Secret

of the universal success of Brown's Iron Bitters is simply this: It is the best Iron preparation ever made; is compounded on thoroughly scientific, chemical and medicinal principles, and does just what is claimed for it—no more and no less.

By thorough and rapid assimilation with the blood, it reaches every part of the system, healing, purifying and strengthening. Commencing at the foundation it builds up and restores lost health—in no other way can lasting benefit be obtained.

75 Dearborn Ave., Chicago, Nov. 7.

I have been a great sufferer from a very weak stomach, heartburn, and dyspepsia in its worst form. Nearly everything I ate gave me distress, and I could eat but little. I have tried everything recommended, have taken the prescriptions of a dozen physicians, but got no relief until I took Brown's Iron Bitters. I feel none of the old troubles, and am a new man. I am getting much stronger, and feel first-rate. I am a railroad engineer, and now make my trips regularly. I can not say too much in praise of your wonderful medicine. D. C. MACK.

BROWN'S IRON BITTERS does not contain whiskey or alcohol, and will not blacken the teeth, or cause headache and constipation. It will cure dyspepsia, indigestion, heartburn, sleeplessness, dizziness, nervous debility, weakness, &c.

Use only Brown's Iron Bitters made by Brown Chemical Co., Baltimore. Crossed red lines and trade-mark on wrapper.

PACIFIC MACHINERY DEPOT.

H. P. GREGORY & CO.,

Importers and Dealers in Machinery and Supplies.

Nos. 2 and 4 California Street, S. F.

SOLE AGENTS FOR

Fay & Co., Wood Working Machinery.
Bement & Son's Machinists Tools.
Blake's Steam Pumps.
Perry's Centrifugal Pumps.
Gould's Hand & Power Pumps.
Perrin's Band Saw Blades.
Payne's Vertical and Horizontal Steam Engines.
Williamson Bros. Hoisting Engines.
New Haven Machine Co.'s Machinists' Tools.
Otto Silent Gas Engines.

Hoisting Engines of all Kinds.

SOLE AGENTS FOR

Starrevant's Blowers and Exhausts.
Judson's Steam Governors.
Pickering's Steam Governors.
Tanite Co. Emery Wheels.
Nathan & Dreyfus' Oilers.
Korting's Injectors and Ejectors.
Disston's Circular Saws.
New York Belting & Packing Co.'s Rubber Belting, Hose, Packing, etc.
Ballard's Oak Tanned Leather Belting.

BLAKE STEAM PUMP.
More Than 16,000 in Use.

The Korting's Injector is the simplest, cheapest and best in use. Will draft its own water, hot or cold, and feed under varying pressure. Send for Circular.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

GOLD MINERS

WORKING PLACER, GRAVEL AND QUARTZ MINES,
SAVE YOUR GOLD!

- BY USING -

SILVER PLATED AMALGAMATING PLATES.

The most economical and successful process now in use. Will warrant my Plates to save more gold than any other method, and double the amount of the same surface of ordinary copper plates. The only plates that have proved durable and satisfactory.

OLD MINING PLATES BOUGHT, TAKEN IN EXCHANGE FOR NEW, OR RE-PLATED.

ALL KINDS OF METAL GOODS PLATED!

San Francisco Gold, Silver and Nickel Plating Works,

653 and 655 Mission St., bet. New Montgomery and Third, San Francisco.

Send for Circular.

EDWARD G. DENNISTON, PROPRIETOR.

Awarded the First Premium at every Fair of the Mechanics' Institute for the last 12 Years.

Pacific Rolling Mill Co.,

LATHES, DRILLING MACHINES, PLANING MACHINES
and Other Machine Tools,

STRONG, DURABLE AND SUPERIOR TO IMPORTED MACHINES.

Wheel Cutting to Order.

SAN FRANCISCO TOOL CO., - - 21 Stevenson St., S. F.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot,

PARKE & LACY,

21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

1850. 1882.

RANKIN, BRAYTON & CO.,
127 First St., San Francisco, Cal.

BUILDERS OF
MINING MACHINERY.

Plants for Gold and Silver Mills, embracing the latest and most improved machinery and processes for ores and free ores. Water Jacket Smelting Furnaces for silver, lead and copper ores, with new and important improvements, superior to any other make. Hoisting Works, Pumping Machinery, Chloridizing Furnaces, etc. We offer our customers the best results of thirty years' experience in this special line of work, and are prepared to furnish the most approved character of Mining and Reduction Machinery, superior in design and construction to that of any other make, at the lowest possible price. We also contract to deliver, in complete running order, Mills, Furnaces, Hoisting Works, etc., in any of the Mining States and Territories. Estimates given on application. Send for illustrated circular.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

—OR—

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ore is an infringement on patents held and owned by the Frue Vanning Machine Company.

That evil has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

VOLUME XLVI
Number 3.

The Heald & Morris Engine

Edward A. Rix, of 47 and 49 Fremont street, in this city, has the agency of the upright and horizontal engines of Heald & Morris. These are efficient, low priced and economically worked engines. All work of a showy and ornamental nature, which enters largely into the costs of engines generally, all complicated and expensive mechanisms for operating the valves, etc., have been practically dispensed with. These things add greatly to the cost, and as engines of this class pass largely into the hands of those quite inexperienced in their attendance, it is absolutely necessary that complicated mechanism should be avoided as far as possible.

As will be seen from the engraving, these engines are of a somewhat novel yet graceful design, giving in the highest degree, for the weight of material used, and which is ample for all contingencies, that strength and rigidity of parts essential to durability and economy in wear, and freedom from vibration and noise when in rapid motion.

The working strain acting on a line through the center is self-contained, rendering it practically impossible for them ever to become out of line. Requiring a very small floor space, they are more compactly built than any horizontal engines of equal power, and from shortness of stroke and great strength of parts, admit of a high rate of speed.

The cylinder is steam-jacketed, with steam chest on bottom, giving perfect and instant drainage, and all cast in one piece. The piston is packed with self-adjusting inside and outside metallic rings. The valve is simple and inexpensive in construction. It is as perfectly balanced as one running in a horizontal position can be made, and requires the minimum of power for its operations. It exhausts through its center into the heater, giving no pressure on steam chest covers nor leakage at any point.

The feed pump is simple and durable; accessible in case of stoppage by simply loosening one nut and without disconnecting pipes. The water heater is a separate part, and so attached as to have no effect from its expansion and contraction on other parts, and has perfect drainage. The engines are furnished with best make of governor, and can be set to make the engine run at any speed desired.

The crank shaft, connecting rod and shafts, are of the best forged iron. Anti-friction metal is used for the shaft boxes and bronze metal boxes for both ends of the connecting rod. The cross-head is of steel with steel wrist and bronze metal gibs adjustable to wear. The piston rod is of steel, and all the material and fittings are as perfect as mechanical skill and good facilities can give. All parts are made in duplicate, so that worn out or broken parts may be readily and cheaply supplied.

There are five sizes of the Heald & Morris horizontal engines sold, from an 8x8 to a 14x12. The engraving shows the "Reliable," which is made from 20 to 45-horse power, with cylinder 10 inches in diameter and 10 inches stroke, and a 53-inch fly-wheel. This engine weighs 2,800 pounds. It requires a foundation seven feet by two feet, and a floor space over all of eight feet four inches by four feet six inches. This is extreme measurement over all projecting parts, including wheels, pipes, pulleys, etc.

Academy of Sciences.

At the last meeting of the Academy of Sciences Prof. Davidson presided and there was a large attendance. Prof. Hitchcock, of Dartmouth College, who has since sailed for the Hawaiian Islands, addressed the Academy on the subject of "Glacial Moraines." He said an examination of the distribution of moraines had prompted an inquiry as to whether they were deposited by glaciers or icebergs. In his opinion, they are clearly the work of glaciers, and icebergs have in certain localities simply supplemented their work. Late observations now enable us to decide the positions of these great terminal moraines. Their extreme eastern boundary is off the island of Nantucket, and they extend, with occasional interruptions, when cut away by streams traversing them, below Long Island, Staten Island, through New Jersey, Kentucky, Illinois, Missouri, Kansas, con-

and clay were formed by high-water rivers, resulting from melting ice, and prove conclusively the claims of glacial theorists. Some such terraces, remaining as steps, must have enclosed rivers 200 ft. deep at such times. Along the line of the Northern Pacific railroad in Idaho and Montana these successive terrace formations are developed on a magnificent scale. They are exceedingly interesting as bearing on the antiquity of the human race, for on these high terraces are found flint arrow-heads, obsidian spear heads and the remains of early man.

He thought there could be no doubt that man lived as far back as the ice period. It was at first supposed by early glacial investigators that all glaciers originated at the poles and worked their way toward the equator. This theory is now untenable, for we can locate the various ice centers on this continent whence these glacial flows have proceeded, and this has also been done in Europe. In the center of our continent

Expenses of Mining Companies.

It was a wise conclusion that the Presidents of the 10 mining companies in this city came to the other day when they met and resolved to reduce the salaries of all officers, including their own, at the same time agreeing to keep the miners' wages at the present standard.

We have often inveighed against what may be called the "top heavy" system of mining, where very high salaries were paid for officials who performed merely nominal duties, and without whom the actual work in the mine itself could very well go on. It has been, however, to the interest of the men in charge, and having influence in this direction, to keep those high salaries running as long as possible, since they participated in the profits and were themselves benefited.

Of late it has come to be recognized that people would have nothing to do with the stocks of these mines, and the occupation of many of these men was gone. Other people refused to pay assessments, and the stock had to be taken by the company, and would bring no price when sold again. It became evident that in order to restore confidence and keep the mines running at all, some popular move should be made to cut down expenses. Many of these expenses ought to have been cut down long since. If they had been, the mines would have been worked to a better advantage, since money spent on useless officers would have paid miners to do work in the mine, where money should be legitimately spent.

It is even now, however, late as it is, a subject of congratulation to all friends of legitimate mining that the evils of the "top heavy system" are being recognized in this city. They are finding out that in order to do anything with mines they must work them. It is no longer possible to work stocks instead of mines as formerly.

People will invest to a certain point and no further. All the dodges of the stock market are pretty well known, and the public has learned by bitter experience that their money invested in this way is all the money of people who are probably interested on the other side.

With the superfluous expenses cut off, and the ordinary ores reduced, the mines themselves have a better chance of getting what they need to be developed. It was a poor way to raise \$100,000 by assessment, and fritter away \$75,000 of it in useless expenditures, the other quarter going to the mine. With the new order of things now going on there is a much better prospect for the mining interests of the coast.

MINING BUREAU.—A bill has been introduced in the Legislature looking to the better support of the State Mining Bureau, which will give it an appropriation instead of having it depend on the tax on mining stock certificates. It is probable that the collection now at Sacramento will be removed to the Bureau here before long.

THE Pacific Iron works, Rankin, Brayton & Co., San Francisco, are completing at their Chicago shops a 30-ton galena plant for the Campbell Reduction and Milling Company, of New York, to be used on the mines of the company in North Carolina.

THE HEALD & MORRIS "RELIABLE" HORIZONTAL ENGINE.

tinuing to an indefinite distance toward the northwest. This general outline traces the extreme terminal moraines, but many others exist within the outer circle at different irregular points formed by the ice boundaries, varied by the difference in seasons.

Another large glacial area is bounded by a point beginning on British territory, extending through Montana, Minnesota, Iowa, Wisconsin, and forming a loop parallel to Lake Michigan and Lake Erie; thence down to Long Island, and off Cape Cod, whence it extends off into the Atlantic ocean. In the ice age the country stood higher out of the water than now, hence some of these moraines are now submerged under the ocean. Fishermen engaged in our Atlantic coast fisheries bring in great numbers of tertiary fossils, brought up from the shoals off the eastern coast of the United States and Nova Scotia. The large glaciers of the great glacial period were thousands of feet in thickness. The very large kettle holes worn by the erosion of boulders throughout the northwest portions of the continent belong to this general system of terminal moraines. Erratic boulders are distributed over the country, having been transported by moving glaciers on their surface, without abrasion from contact with the surface. He said many claimed that terraces of gravel, sand

there existed at least three pre-historic lakes of great magnitude, which were recently named for purposes of identification. Lake Bonneville was as large as the Territory of Utah, and is said to have been the result of melted glaciers. Lake La Hontaine was another glacial lake between the Sierra Nevada and Rocky mountains. Lake Agassiz was a similar lake in Minnesota, whose extreme southern part was once the source of Red river. These three lakes, long since drained and dry, were glacial lakes.

Mr. J. G. Lemmon read a paper describing the native potato of Arizona. This paper we shall refer to in a future number.

ANNUAL MINING REVIEW.—We shall publish next week a double edition of the MINING AND SCIENTIFIC PRESS containing our "Annual Mining Review." There will be a good deal of interesting matter in this edition for the miners of the coast, each of whom should have a copy. The statistics of production, so far as gathered, will be printed, and the number will be especially valuable for reference.

CONGRESSMAN ROSECRANS says that the Ways and Means Committee have admitted being in error in putting boracic acid on the free list, and they will change their recommendation on the subject.

Southern Nevada.

During our trip through the southern part of Nevada we were surprised at the number of reduction works that had been erected in the different mining camps and laying idle, monuments of folly and mismanagement. If one-fourth the amount of capital had been expended in exploring the mines that has been wasted in erecting those expensive works, our State would to-day be the greatest bullion producer in the world. Valuable mines are lying idle, which, if worked on legitimate business principles, would be dividend payers, but useless expenditures and gross mismanagement have caused stockholders to refuse to contribute any further funds, and the mines and mills have become almost uninhabited, where heretofore all was life and bustle, and not on account of the merits or demerits of the mines, but simply from the incapacity and make all you can for yourself management. Nevada has had "wild cat and stock jobbery" enough, while our neighboring mineral States are enjoying a season of prosperity. Nevada is undergoing a season of dullness unparalleled in her history, and through no fault of her mines or mineral wealth. We believe that our State is the best mineralized State or Territory in the Union, if properly worked, and in all our principal mining camps it has been proved beyond a doubt that our mineral veins are continued to as great a depth, as in any other country in the world. Then why should so many of our mines be lying idle to-day? Let any person who has been a resident of those camps answer the question. Is it through the mines giving out, or account of the poorness of the ore? Can they truthfully say yes in either case? There may be some few exceptions, but the greater number will have to be laid to the incapacity of the management and useless expenditures in salaries to non-producers. How many mines are there whose pay-roll for miners and mill men can equal the amount paid out to supernumeraries, many of whom have never seen a mine and know no more about mining than a cow does about handling a musket. Mining can be made a paying business, and will pay a larger rate of interest on the amount invested than almost any other business, but must be conducted on the same business principles that any other business is conducted on. Then, and not till then, will our State return to its old time prosperity, and it should be the endeavor of all interested in mining and the welfare of the State of Nevada to do all in their power to encourage legitimate mining and discourage wildcat schemes and stock jobberies.—*Levis Herald*.

Vertigoid by the Geologists.

This is the way that the spokesman at a miner's meeting in the Gibraltar mining district, near Casa Grande, put it:

"Fellow miners and citizens: I am not Fitch, the silver tongue, nor am I Beech, the Plymouthian; but I am the rhetorician of these little hills and the vindicator of the miner's wrongs. Egypt had her ten plagues; Pharaoh was swallowed in the Dead Sea, and Beecher swallowed Plymouth church; but greater curses are reserved for Arizona. The locusts from the East, having professional appendages, are now lighting upon our mining camps and darkening our brightest prospects with their inexperience and unjust reports. What do strangers from the East know about our peculiar country? They acknowledge that our veins and ledges are totally new to them, and the pitch of our hills are so peculiar that they have never seen a similarity of them before, and yet, in the face of all these assertions, they render an off-hand verdict on our mines with as much ease and gusto as if they were dining upon roasted turkey. They are shown some of the richest veins and lodes in Arizona, and yet because two or three millions have not been expended in tunnels, winzes and dumps, they turn up their facetious noses, pass sentence derogatory and repack their satchels for civilized Boston. The miner has said more than once, and still repeats it, that the capitalist should be the party acting in these matters; the book student mineralogized and metallurgized let loose from the bank counters and office space of eastern cities are nauseated at the presence of an Arizona desert, and their book-stuffed learning and theories theoretical are dealt out to the hardy-fisted miner in such doses and pills that it seems all practical experience was at nought and only learned men resided in the East. Fellow citizens, am I not right when I say that Arizona is sick, vertigoid by the professors and stupefied by the geological geologists? (Cries of, 'Bravo! good, good, 'tis so, give it to 'em.') My friends, in the future let us place a plate, knife and fork at the miner's table for the reception of the man of means and practical business knowledge who will meet us half way upon reasonable propositions, and let us ignore and banish the learning that stands on hill tops and knows it all. (Great cheering and cries of 'We'll fix 'em.')"—*Tombstone Independent*.

ALCOHOL FROM CHICOORY.—Chicoory will hardly be longer made to serve as a substitute for coffee if it is true that, as a European technical journal asserts, it can be made to give an alcohol of a pleasant aromatic taste and great purity.

Mexican Mining Laws.

We republish from the *Denver Tribune* the following précis of the mining laws of Mexico, contributed to that journal by its intelligent traveling correspondent, "Weaver," written from the city of Chihuahua:

"For the instruction of those of our people who have an eye to mining in Mexico, I have been at some pains to gather correct information as to laws governing mines. There is a difference of opinion here between native lawyers and American interpreters as to the meaning of the mineral laws, especially that part of them which refers to the length of time a mine must be worked during each year, some claiming that a mine must be worked at least eight months, and others four months in each year. I am indebted to Señor Martínez del Río, Jr., an attorney in the city of Mexico, for my interpretation of the mining laws. And I will preface the summary of them by the remark that our own mining laws might be greatly improved by modeling them in some features after the Spanish laws. These laws seem to be particularly adapted to the development of the mineral wealth of the country, whereas ours allow of the longest delay, and even of the holding of the most valuable mines without any production whatever. As is well known, Mexico was captured and held by the Spaniards for its mineral wealth, and the laws the Spanish Government enacted governing mines were with a view to obtaining the greatest production of bullion. Under the old Spanish laws, which are held in observation by the States of the Republic, the right of eminent domain in mineral whether on private or public lands, was always reserved to the government, and no individual or corporation could become the owner of mineral in the earth. The government grants the privilege of working out the mineral under certain fixed conditions, and when these conditions are violated the privilege is withdrawn. These conditions may be briefly stated as follows: The discoverer of an ore body of mineral denounces (claims) the discovery, and must publish or advertise his denouncement after having first established his boundaries. He must then sink a shaft or tunnel 30 ft. on the ledge within 90 days. Then in 30 days more he must dig 30 ft. more. A justice then goes in company with a mining expert, examines the property and measures off 200 yards along the vein, and 200 yards across it, the side lines being located according to the inclination of the vein. If the vein is perpendicular, 100 yards are allowed on each side. If horizontal, 100 yards square are allowed. If the vein dips 45° they measure 150 yards on side of dip from the outcrop, and 50 yards on the other side. The claimant is then put in possession, with a title to the mineral, under the proviso that he must work the mine at least four months in every year, with not less than four men. If he fails to do this work he forfeits all his rights and all work, and the mine may be denounced and taken possession of by the first comer. The mineral wealth does not belong to the general Government, but to the States. The States, however, have retained the old Spanish laws, as proven by experience to be the most wise and best adapted for the development of the mines. The ownership of lands does not affect the right of government to the mineral beneath them, only that the discoverer of mineral on private lands must pay the owner for the surface at its value. The water and timber privileges go with the mineral. Here is, in brief, the essence of the mineral laws of Mexico. With similar laws in force in our country, I believe that the bullion product of Colorado would to-day be quadruple what it is. It seems preposterous that Government should carry the title to mineral lands to individuals or corporations, as is often done in the United States, for no other object than that they may keep somebody else out of possession, or to work stock speculations, or for no object whatever apparent other than the mere desire to own a mine. It is a well-known fact that hundreds of the richest mining claims in Colorado are held under Government titles, and are not producing a dollar of bullion in years. Under the Spanish laws these gentlemen would either have to produce something from the mines or abdicate in favor of somebody else."

THE ÆOLIAN HARP consists of a long, narrow box of pine about 6 inches deep, with a circle in the middle of the upper side of 1½ inches in diameter, in which are to be drilled small holes. On this side 7, 10 or more strings of a fine cat-gut are stretched over bridges at each end, like the bridge of a fiddle, and screwed up or relaxed with screw pins. The strings must all be tuned to one and the same note (D is perhaps the best) and the instrument should be placed in a window partly open, in which the width is exactly equal to the harp, with the sash just raised to give the air admission. When the air blows upon these strings with different degrees of force it will excite different tones of sound. Sometimes the blast brings on all the tones in full concert and sometimes it sinks them to the softest murmurs. A colossal imitation of the instrument just described was invented at Milan in 1786, by the Abbe Gattoni. He stretched 7 strong iron wires, tuned to the notes of the gamut, from the top of a tower 80 feet high to the house of a Signor Moscati, who was interested in the success of the experiment, and this apparatus, called the "giant's harp," in blowing weather yielded lengthened peals of harmonious music. In a storm this music was sometimes heard at a distance of several miles.

Sierra County Mines.

The Sierra county *Tribune* says: It is often a matter of great surprise to many who visit Downieville and notice the unusual advantages offered in its vicinity for quartz miners that no enterprises of this character scarcely are in operation. The first conclusion reached is that there are no ledges in the section worth developing. However, the contrary is the case, and these visitors who do not take the pains to inquire regarding the matter become impressed with false ideas. Of course, these men, with their unfavorable opinions, often work injury to this section on the outside.

On the mountain sides leading north and south from Downieville are numerous ledges that have been prospected, and in many instances they have been developed sufficiently to prove that the rock is of a high character. Too often, however, these ledges have fallen into the hands of poor companies, whose only object in securing them was for corrupt purposes. If these companies could make nothing by other means than legitimately working their properties, then the ledges were abandoned, and, as a matter of course, they are looked upon to-day by those from abroad as worthless.

With the exception of the Gold Bluff there is not a quartz mine in operation to-day near this town. S. Van Slyke, the owner of the Gold Bluff, has alone run this mine and made it one of the best dividend-paying properties in the county. On the other hand is the Good Hope mine, owned by a San Francisco company (purported to be wealthy), who came up here last year and displayed all the pomp imaginable. They erected a fine 20-stamp mill (which was heavily insured), coyoted around in former worked-out drifts for a while, and then then the mill was burned under very suspicious circumstances. The mine is now lying idle, not one iota more prospected than it was the day that the company assumed control of it. Experienced miners say that the Good Hope can be made a paying mine if properly developed.

It does seem to us that if the business men of Downieville would make an effort they might have some of these mills that are lying idle within almost a stone's throw of the town in operation. If the real facts were presented to legitimate mining operators, and the business men would lend their influence, in all probability the desired object could be accomplished. The people of Downieville have been deceived many times by fraudulent companies, but if they would take the matter in hand themselves they might avert so much of this deception in the future. With the utmost confidence in the value of the surrounding mines, and knowing of what benefit they will prove to Downieville, if properly worked, our citizens should endeavor to attract the attention of honest investors to this section, while on the other hand they should endeavor to keep away all companies whose objects have the odor of rascality.

THE ACTION OF LIGHT UPON AMALGAMATION.—M. P. Laur, of Rodez, Aveyron, France, having noticed in Mexico the striking effect of the sunlight upon the activity of the process of amalgamation, has undertaken a number of experiments, which he has communicated to the French Academy of Sciences recently. He placed in a dark chamber a glass vessel containing a solution of 15 parts of salt and 7 parts of sulphate of copper in 100 parts of water. A porous vessel filled with quicksilver was suspended in this solution, and one platinum electrode was dipped into the mercury, while a second, consisting of a leaf of sulphide of silver, was dipped into the copper solution. The wires from both are connected with a galvanometer. When the vessel is placed in the dark chamber and the circuit is closed, the needle of the galvanometer is deflected, showing that the sulphide of silver is the positive pole. As soon as light is admitted to the dark chamber, the needle at once swings back, the current being still in the same direction. Every change from darkness to light, or even in the intensity of the latter, causes variations in the current. The bichloride of copper formed by the mixture of salt and sulphate of copper attacks the quicksilver, and the photo-chloride of copper formed reduces the sulphide of silver. This reduction, however, takes place only under the action of sunlight, and therefore an electric current is produced by exposure to the sun.

AN IMPORTANT INVENTION.—A new process in the manufacture of alkali has just been invented by McTear. The main advantage of his new patent is that it admits of the use of ground rock salt, which is a great saving compared with the white salt. It is said it produces a much improved quality of salt cake. At the same time it effects the decomposition of salt at one-third the cost of the present system—hand labor. This marks an important point in the chemical manufacturing trade of the Tyne district, for if it is successful, as it promises to be, many employers will be able largely to diminish working expenses.

SUBSIDY TO PASTEUR.—The French Minister of Agriculture has lately placed at the disposal of M. Pasteur a new sum of 50,000 fr. (\$10,000) in order to continue his admirable investigations upon the contagious diseases of animals. The Government had already granted to the illustrious savant, for the same object, 50,000 fr. in 1880 and 40,000 in 1881. The minister consulted a special committee, who, in view of the brilliant success obtained by Pasteur in his previous investigations, unanimously recommended a renewal of the grant.—*Les Mondes*.

Air in Mines.

There are two principles which are relied upon to ventilate a mine. That of heat expanding the air and the abhorrence of a vacuum by nature. Add to these a system of pumping or forcing air into a place, and we have the three ideas upon the expansion of which into practical methods all ventilation of mining properties depends. There are various cansees which develop heat in mines. The lamps or candles by the light of which the miner works, the heat given out by the hodies of the men as the result of that work, the oxidation of sulphur, if any be present in the mineral or in the walls, being among them. There may be, too, the heat of thermal springs, or, if the mine be deep enough, that which is found in the rock. If we suppose a shaft to be sunk, say 2,000 ft., and if in the center of that shaft we placed a tube, or box, or any substance, wood, for example, which runs from the surface of the ground to the bottom of the shaft, there would be at once created a circulation of air. The air around the sides of the shaft being heated by the walls would rise, and the vacuum so created would draw the cold air down through the box. But if we kindled a fire below the box, the current of air would be down the shaft and up the box.

The system of ventilating a mine by heat is simply the one which we have imagined expanded to the extent necessary to ventilate the whole mine. If we run off at one side from the bottom of our shaft a level of 500 ft. in length, and carried the box into the face of it, we would have precisely the same thing taking place as before. The air, as heated by the walls, would travel along the level and ascend the shaft, while the cold air would come through the box. If instead of constructing a box we placed a division in the shaft, cutting it into two equal parts, as we do so often in this country, the cold air would descend on one side and the warm air would ascend on the other. Suppose, however, that we had two shafts—one at each end of the level; then the air would come down one, traverse the level and go up the other. The direction in which it would travel would depend altogether upon the size of the shafts or the amount of heat generated. If the shafts were of unequal size the air would come down the smaller and go up the larger. If it is the same the air would move in the direction of that shaft the center or the equilibrium of heat was nearest to. If the center or equilibrium of heat was exactly in the center of the level, and if the friction on the air was exactly equal in each shaft, then we could cause the air to move whichever way we pleased by building a fire at the foot of the shaft we wished it to ascend. Keeping that fire burning for a day would be sufficient to cause the air to ascend that shaft in preference to the other for all time, because the cold air constantly descending through one shaft would cool that shaft off and so move the point of equilibrium of heat nearer to the other.

The ventilation of a mine where pumping is not necessary is merely an expansion of the system which has just been outlined. But there are two most important variations possible in the application of this system. We may either take the fresh air in through a box to the workings or we may take the foul air out. Each has its advantages. In the first we find the introduction of the fresh air and the removal of the foul easier than in the second. In the second the foul air and gases generated by blasts are carried off at once and are not forced to travel through the level to the shaft.

A SPECTACULAR COLLECTION OF ORES.—At the office of H. M. Yerington, General Superintendent of the Virginia and Truckee and Carson and Colorado Railroad, at Carson, is to be seen a rich and beautiful collection of samples of ore from the mines situated in the mineral ranges bordering Owens Valley. These ore samples were collected by Mr. Yerington during a recent trip through that country along the line of the Carson and Colorado road. There are specimens of silver, copper, argentiferous galena and free-gold ores. Many of the samples of copper are very beautiful, showing brilliant hues of blue, green, orange and burnt sienna. These are not only very rich in metal, but also quite ornamental, making magnificent cabinet specimens. One of these fine samples of copper ore is from the Hirsch mine near Independence, and another from the Russ mine, Bishop Creek. From the Union mine, Cerro Gordo, there are specimens of argentiferous galena that are solid masses of metal. This ore runs very high in silver. From the Farrington mine, near Benton, are specimens of chloride ore which are rich. The ore of this mine, now being worked at the Millner mill, Benton, will pay \$200 per ton. From the Poleta and Sacramento mines—both very fine properties—there are specimens of quartz that show very bright spangles of free gold. In short, mining men will be able to obtain a very good idea of the mines in the Owens Valley country by an examination of this collection of ores. Many mines not mentioned above are represented in the collection.—*Evreka Sentinel*.

A CABLE RAILROAD FOR PHILADELPHIA.—Work on the machinery to be used in furnishing the motive power required to operate the first cable street railway in Philadelphia is now rapidly progressing, and it is expected that all necessary preparations will soon be completed.

MECHANICAL PROGRESS.

SELECTING AND USING BELTS.—There are several hundred columns published every year in newspapers on the subject of belts, mostly giving directions how to use them and how to take care of them. But the first thing to be considered is how to select them; for if a man does not know how to select a belt, an article in a newspaper will not teach him much on this subject. A belt is either too small for its work, too large, or just right. It is a difficult matter to tell the exact power required for different machines, because the required power differs at different times in the same machine with the quality or quantity of work to be done. If a belt slips it proves that the traction surface is too small, either from small pulleys, deficiency of circumferential contact or narrow belts. The way out of this is clear; but the practice of putting compounds on belts to keep them from slipping is a narrow, senseless one. There are a few manufacturers who make first class belts and make them all the time, and any one who buys from them is sure to buy a good article. It is a very difficult matter to judge a good belt by looking at it. It is doubtful if any one can judge accurately who is not handling leather as a business. There are a few firms whose business is to make good belts, and they do it. The way out of the difficulty is fixed. Where the power is known, a belt of sufficient size to transmit that power can be determined.

AN ASPHALT MORTAR.—A German paper describes a patented composition made at a factory in Stargard, Pomerania, which has for some years past been used with perfect success on the Berlin-Stettin railway for wall copings, water tables and similar purposes requiring a water-proof coating. The material is composed of coal tar, to which are added clay, asphalt, resin, litharge and sand. It is, in short, a kind of artificial asphalt, with the distinction that it is applied cold, like ordinary cement rendering. The tenacity of the material when properly laid, and its freedom from liability to damage by the weather, are proved by reference to an example in the coping of a retaining wall which has been exposed for four years to the drainage of a slope 33 ft. high. This coping is still perfectly sound, and has required no repairs since it was laid down. Other works have proved equally satisfactory. In applying this mortar, as it is termed, the space to be covered is first thoroughly dried, and after being well cleaned is primed with hot roofing varnish, the basis of which is also tar. The mortar is then laid on cold to the thickness of about three-eighths of an inch, with either wood or steel trowels, and is properly smoothed over. If the area covered is large, another coating of varnish is applied, and rough sand strewn over the whole. The water-proof surface thus made is perfectly impregnable to rain or frost, and practically indestructible. The cost of the material laid is estimated at not more than 5d. per square foot, and it is stated that this price can be reduced by at least 1d. for large quantities put down by experienced workmen.

A NEW METHOD OF MAKING RAILWAY SPIKES.—The machine used in the manufacture of railway spikes by H. H. Fowler & Co., Chicago, consists of two large rolls, mounted in substantial housings, and driven by gearing after the manner of ordinary bar rolls. The center of these rolls contains a groove in which the forming dies are placed. These are twelve in number, are made of special grade of steel and contain the imprint of the spike. The spike, after being rolled into the groove, is forced out by the plunger actuated by interior methods. The rolls are driven at such a speed that the radius of the roll is not assumed by the spike, but it leaves the roll substantially straight. The speed also has the effect of forming the spike, as it were, by a blow. The entire operation of producing the spike consists merely of taking from the furnace the hot billet, about two inches square, running it through but four passes, after which it is fed direct into the spike forming rolls, from which the spikes drop out automatically, at the rate of twelve per revolution. The machine is capable of turning out from 600 to 1200 finished spikes continuously per minute, depending upon the rate of speed at which the machine is run.

KEEP YOUR MACHINERY CLEAN.—It might be urged that in some shops where they want quantity more than quality, no time is allowed to wipe or clean a machine, and the foreman is indifferent how short lived a machine is. In any shop where first-class work is done, a careful mechanic who does his work so that no one can do it better, and takes good care of his machine, will always be appreciated. A man who tries to make short cuts by dumping or grinding a little off the extreme edge of his tools, and works with the points a quarter of an inch lower than the back, is invariably a butcher.

MALLEABLE BRASS.—A German periodical is responsible for the following method of making malleable brass: Thirty-three parts of copper and 25 of zinc are alloyed, the copper being first put into the crucible, which is loosely covered. As soon as the copper is melted, zinc, purified by sulphur, is added. The alloy is then cast into molding sand in the shape of bars.

USE BOTH HANDS.—A writer on mechanical subjects advises young mechanics to cultivate the nerves and muscles of each hand so that they can use a hammer, chisel, file, wrench, or any other tool as well with one hand as with the other; or so that they can turn a handle or hand wheel one way with one hand, and another one the other way with the other hand, both at the same time, or so that they can turn them both one way or different ways at different speeds. Such practice in turning handles will be found indispensable in learning to become an expert on the lathe, planer or other machine tool. All that is required to learn this is a little practice until the motion of one limb or member is not at all governed or controlled by the motion of another.

A NEW TRAM CAR.—At a Bavarian exhibition in Nuremberg lately there was shown, from Noell's wagon manufactory at Würzburg, a tram car which does not require switch and siding on meeting another car. The car is kept on the rails by means of a fifth wheel in front of the others, and catching in a groove between the rails. The guide wheel is set in a triangular frame on the fore axle, and when the driver raises this the car readily leaves the rails, and may be drawn over the street pavement in any direction. Such cars have been successfully used in Hamburg and Lisbon. Of course, the leaving the rails involves greater strain for the horses, but this is only temporary and without serious inconvenience.

WONDERFUL IRON MAKING PROCESS.—M. Bartholmy Brunow, a French metallurgist, is credited with having discovered a method of reducing iron ore to pig metal in the short space of 14 minutes. A lump of African iron ore, weighing 32 pounds, was broken up into small fragments and placed into a crucible. As soon as the ore was at red heat, a reacting substance was added, and in three minutes the liquefaction was complete. The produce obtained was iron. The reacting substance cost about 25 cents per ton. What the reducing substance is has not been stated.

THE Pullman Company are about to engage in the manufacture, on an extensive scale, of freight cars, and have already received orders for some 4,000 cars. Work is now in progress on 10 dining cars for the Northern Pacific, and 6 dining and 6 sleeping cars for the New York, West Shore and Buffalo road. Enough orders are on hand to keep the shops busy for the next year, among the largest of which are 60 first-class and 37 second-class passenger coaches for the Northern Pacific, and 50 passenger and 20 baggage and mail coaches for the West Shore road.—*Industrial World*.

THE FINISHING FILE.—In the hand of one who appreciates its possibilities, a three-cornered file, ground sharp on the sides and rounded toward the end like a bayonet, is a most efficient finishing tool on fine work. It will take out every scratch and leave dead smooth surfaces that require but little rubbing with emery paper. The scraper does not cover up the work as the file does, and is much more speedy in action. Used with saliva on wrought iron or steel it surpasses any other tool for finishing.

AN IMPROVED WOOD SCREW.—Screws used in soft wood are sometimes driven in with a hammer, and given a turn or two with a screw-driver to bring them flush. A manufacturer has brought out a new screw which is adopted for driving and which enters the wood without tearing the grain as the ordinary screw does. The gimlet point is dispensed with and a cone point substituted. The thread has a pitch that it drives in barb fashion, offering no resistance in entering, but firmly resisting all attempts to withdraw it except by turning it with a screw-driver.

SLOTING SCREWS.—A New York City firm has invented a simple machine for rapidly slotting screws, which is said to work satisfactorily and cheaply. It operates so as to require only one downward pressure on the lever to grip and slot the screw. When the lever is released, the screw head is clear of the saw before the jaws relax, but when the lever has reached a certain point, the screw drops out and the jaws are ready for another. The jaw is readily adjustable, and screws of different diameters can be slotted without delay in changing the parts. The machine, which weighs 250 lbs., can be used in milling certain classes of light work.

FROST AND FRACTURE.—Additional tests made by M. Bacle seem to prove that low temperature has but little to do with the fracture of railroad tires. Other things being equal, the tires are as strong, he says, in severe frost as when the temperature is normal; but low temperature increases, of course, the rigidity of the road and its inequalities, and so renders the shocks received by the tires very violent, producing at times disasters which are attributed to changes in the metal.

NAIL MILLS.—In the eastern part of Massachusetts, and with headquarters in Boston, are seven nail mills, operating 300 machines and turning out an average of 10,000 kegs per week, mostly for the home trade, but furnishing shipments for Cuba and South America.

SCIENTIFIC PROGRESS.

The Origin of Life.

Men of science may amuse themselves by speaking of life being brought to the earth by the arrival of a meteor, in reality a fragment of some once peopled world which has been destroyed by conflict with another or by internal disturbance. But this is a more scientific jest than a grave reality. Astronomy knows nothing of worlds coming into conflict. On the contrary, the laws of motion assure us that if anything is so unlikely that it may be regarded as absolutely impossible, it is the encounter of two orbs in mid space; nor have we any reason to suppose that a planet can be rent into fragments by internal convulsions. If we had, we have not the slightest reason for supposing that orbs thus unfortunate would be more likely to be inhabited than their more lucky fellow worlds. If these were inhabited already, we gain nothing by bringing to them the fragments of other worlds which have exploded; and if they were not inhabited, whilst the burst or shattered worlds were, we are called on to imagine (for no one can believe) the absurdity that only inhabited worlds are liable to destruction, for the benefit of those which are without inhabitants. To which absurdity this additional one is superadded, that the seeds of life would survive the destruction of their planet home, and the journeying through millions on millions of years (rather millions of millions) which science assures us they would have to make through the cold of interstellar space before they would fall on any other world. And all these absurdities to no purpose, so far as the origin of life is concerned, for they take us back but a step, which brings us in reality no nearer to all life.—*Professor Proctor, in Belgaria*.

SIEMENS' NEW SOLAR THEORY.—The solar theory lately propounded by Dr. Siemens, President of the British Science Association, does not meet with favor in the eye of Dr. Tyndall, the eminent physicist. Dr. Siemens suggested that interstellar space is filled with various combustible gases, which are drawn in by the sun in its onward march; that these gases rush in from the pole of the sun toward its equator, producing intense heat by their combustion on the sun's surface; that the products of this combustion are then thrown off into space, where, in a highly rarified state they are dissociated by the solar rays and are once more ready to become fuel for another sun. In commenting on this theory Dr. Tyndall says: "It would give me extreme pleasure to be able to point to my researches in confirmation of the solar theory recently enunciated by my friend the President of the British Association. But through the experiments which I have made on the decomposition of vapors by light might be numbered by the thousand, I have, to my regret, encountered no fact which proves that free aqueous vapor is decomposed by the solar rays or that the sun is reheated by the combination of gases, in the severance of which it had previously sacrificed its heat."

NEW SAFETY LAMP.—M. Tricot, the manager of the Mons gas works, at the recent meeting of the Association des Gaziers Belges, described a new fixed lamp invented by M. Lechiem for burning safely while surrounded by an explosive mixture of air and gas, such as may be present in gas works. It consists of a metal bracket (with an orifice in connection with a pipe leading a supply of pure air from a safe distance) securely fixed to the wall, and provided with a groove filled with sand for receiving a projecting collar at the bottom of the lamp, so as to form an air-tight joint. In the bottom of the lamp is a valve, opening inwards, which keeps it closed until placed in position, when it opens automatically. The cover, made separate for facility of cleaning, is also provided with a sand joint, and the trunco-conical chimney is of such dimensions that no air or gas can enter the lamp by its means; while a sheet of perforated metal or wire gauze, placed across it, affords an additional safeguard. When the source of light is a vegetable or mineral oil, the lamp has simply to be lighted in a pure atmosphere before being placed in position, as it contains sufficient air to support combustion for two or three minutes, when the air valve opens. When ordinary coal gas is used, the simplest method is to light a small piece of taper near the burner before fixing the lamp, and making the connection with the gas supply pipe; or the gas may be lighted by electricity, or by a fulminating capsule.

A PRETTY SCIENTIFIC EXPERIMENT.—The following experiment in the way of physics without apparatus is given by a correspondent of *La Nature*. A clay pipe is laid over the top of a large wine glass, and a person is required to bring it down to the table without touching either pipe or glass, without agitating the air or moving the table. The solution of the problem consists in taking up another like glass, rubbing it vigorously on your sleeve, then bringing it near the pipe stem, which is thereupon strongly attracted, so that the pipe falls. This experiment is a pretty variation of the electric pendulum, and shows that pipe-clay, a very bad conductor of electricity, yields readily to the attraction of an electrified body.

M. NORDENSKIÖLD maintains that the aurora is a permanent phenomenon in polar regions, being always seen when the sun is below the horizon and when the moon is invisible.

SPECULATION IN ELECTRICITY.—It is not only the inventors of the world that have now turned their thoughts to electricity, but also the speculators. The progress of the practical science to that degree of industrial perfection which will render it a paying investment from a financial point, is necessarily slow. Some companies have indeed established themselves almost at once as profitable undertakings; but the formation of large money enterprises, on the strength of inventions which are not sufficiently tested, is certain to result in disappointment. The quotations of some of the minor English companies have greatly depreciated. In fact, electricity, though a giant, is yet young, and should not be made a favorite object of speculation. We are in favor of the widest freedom, so far as manufacturing enterprise is concerned, for here there is a solid basis, but the abuse of electric discoveries in England by the "promoters of the undertakings" has already thrown some discredit on solid companies. The shares of some of the branch companies that were formed have declined considerably, others have been obliged to wind up. But whatever stock jobbing misfortunes may be reported, we have no doubt that when electricity comes to be more adapted to all industries, as it will be before long, it will then offer a large and safe field of investment.

SINGULAR LABORATORY EXPLOSION.—E. Miltz, writing from the Leverkusen Alkazine Works, gives an account of an explosion under unusual circumstances: "I take the liberty of reporting to you a peculiar explosion which has taken place in this laboratory. For a number of years I have prepared the chronic acid solution requisite for the analysis of anthracene by adding to five kilos. of chronic acid water and acetic acid in suitable proportions and letting the mixture stand, stirring occasionally, till the whole is dissolved. One bottle of chronic acid, on addition of the acetic acid and water, became suddenly warm, and in a short time began to boil briskly, giving off abundance of fumes smelling like aldehyde. As I saw that the reaction became more and more violent, and that the chronic acid could not be saved, the room was at once evacuated, and scarcely was everyone out of danger when a violent explosion ensued, with formation of dense clouds of chronic oxide. The chronic oxide was of a very loose texture, exactly resembling that formed on heating ammonium bichromate. A fresh quantity of chronic acid (obtained at the same time with the spoiled lot) dissolved quietly in the acetic and water. I am unable, therefore, to explain the cause of the explosion.—*Chem. Rec.*"

NEW PHOTO-ELECTRIC BATTERY.—A new battery, which gives a current on exposure to the action of light, has been devised by M. Saner. It consists of a square glass vessel, containing a solution of fifteen parts common salt and seven parts sulphate of copper in 106 of water. A porous vessel of mercury is placed in the solution. An electrode of platinum is in the mercury, and another of sulphuret of silver in the saline solution. The electrodes are connected by means of a galvanometer, and the battery is fixed in a box sheltered from light. The closing of the circuit displaces the needle of the galvanometer, and it is seen that the sulphuret of silver is the negative pole. When the needle has come to rest, if the battery is exposed to the light of the sun the deviation increases. If the light is suppressed the needle returns to its original position; if a cloud passes before the sun while the battery is exposed to the light the variations of the needle indicate the fluctuations of the electric current. The effect of the battery is due to the action on the mercury of the bichloride of copper formed by the mixture of common salt and sulphate of copper. The proto-chloride of copper which is formed reduces the sulphuret of silver, but this reduction requires the intervention of the solar light, which determines the production of the photo-electric current.—*Les Mondes*.

The largest telescopes in the world are in the United States, the one at the naval observatory in Washington being 33 ft. long, and there is one of the same size at the University of Virginia, in Charlottesville. But the Russian Government is now having a telescope constructed, to be ready this month, which will be 45 ft. in length. The work is being done by Messrs. Alvin Clark & Co., of Cambridge, Mass., under the care of the great astronomer, Otto Struve. It is for the Government observatory in a suburb of Moscow, but will stand in a meadow outside of the principal building. The diameter of the glass is 30 inches.

PROFESSOR KOCH'S DISCOVERY DISPUTED.—At a meeting of the New Orleans Pathological Society Nov. 20th, the President, Dr. H. D. Schmidt, made an important microscopic demonstration to disprove the reported discovery of Professor Koch, in Berlin, as to the bacilli of tuberculosis. Dr. Schmidt claimed to demonstrate that the bacilli thought by Dr. Koch to be the cause of tubercular consumption were simply fatty crystals. Dr. Schmidt's researches have been long and minute, and he is confident that Dr. Koch is in error.

THE GROWTH OF LANGUAGE.—Human languages appear to have grown like trees in a wood, which in the first stage are as numerous as possible, but are soon reduced to a few individuals, of which a very small number attain their full term of life. Numerous as were at first the local manifestations of human beings, the primordial languages were as innumerable.—*M. Julien Vinson*.

Table of Highest and Lowest Sales in S. F. Stock Exchange

Mining Share Market.

The sudden disappearance of the Secretary of the Albion Mining Company with some of the funds of the mine has created a ripple of excitement in stock circles, but the fluctuation of stocks themselves have amounted to little. The Pacific Stock Exchange has this week sold its building, and will hereafter rent the premises instead of owning them.

The east crosscut on the 2,900 level of the Sierra Nevada, joint with the Union Consolidated, is now but fairly out of reach of the station, and far enough away to allow of heavy blasting being done. It has yet a long way to go to reach the point where should come down the ore streaks out above the winze.

The joint Mexican and Union Consolidated east crosscut on the 2,900 level shows a steady increase of quartz that carries metal. It will be some four weeks before it will hear the point where it is hoped to find ore.

The west crosscut on the 2,500 level of the Gould and Curry is being pushed at the rate of about 60 ft. per week toward the west wall, against, or in front of, which ore is likely to be found.

The following are the financial balances of the various mining companies on January 1st, so far as reported below:

Cash on Hand.—Alta, \$8,505.68; Best & Belcher, \$30,044.19; Benton Con, \$4,650.54; Bechtel, \$9,304.34; Belding, \$336.93; Bulwer Con, \$15,372.30; Bodie Con. (bullion on hand, \$4,302.88); \$25,928.32; California, \$33,993.94; Con. Virginia, \$104,201.90; Chollar, \$29,278.06; Crown Point, \$20,886.03; General Jackson, \$830.98; Gould & Curry, \$17,642.40; Hale & Norcross, \$19,479.19; Lady Washington, \$1,179.58; Mexican, \$45,064.92; Mount Diablo, \$3,075.38; Northern Belle (unsold bullion on hand, \$152,400.50), \$34,418.11; Ophir (bullion on hand, \$15,744.04), \$1,336.81; Oro (indebtedness, \$3,953.14), \$98.05; Occidental, \$6,983.09; Potosi, \$23,255.50; Savage, \$29,872.29; Scorpion, \$107.62; Standard, \$91,581.14; Union, \$6,700. Indebtedness.—Argenta, \$2,883.79; Betty O'Neal (overdraft), \$7,050.67; Grand Prize, \$3,970.99; Mono, \$1,587.80; Sierra Nevada, \$7,485.70; Star (old indebtedness, \$36,839.84), \$34,170; Utah, \$6,543.38.

THE HYDRAULIC ELEVATORS in use in this city in which a long piston, fitting on a cylinder sunk in the earth, carries the cage on its upper end, were invented originally by M. Leon Edoux, of Paris, France. Elevators of this kind were shown in operation at the Paris Exposition of 1867. Several minor improvements have been made since the original invention. This style of elevator is now very popular in this city. Those in the Huuington, Hopkins & Co.'s building, on Market street, which were put in by the California Machine Works, are noticed by many passers. These works also put elevators in the Buai B'rith hall, Eigenbaum & Co.'s, the Sub-Treasury and other buildings,

Meetings and Elections.

BLACK DIAMOND COAL CO., Jan. 15th. President, P. B. Cornwall; Directors—Thomas Bell, P. B. Cornwall, J. B. Haggan, A. Hayward, S. P. Smith. James H. Robinson, Secretary.

BELLINGHAM BAY COAL M. CO., Jan. 15th. Directors—Thomas Bell, P. B. Cornwall, J. B. Haggan, A. Hayward, S. P. Smith. At a subsequent meeting of the newly-elected Board, P. B. Cornwall was elected President and Jas. H. Robinson Secretary.

He ordered the discharge of about 35 men altogether, leaving but 16 miners now at work. As near as the facts can be ascertained, this was simply to reduce expenses pending the erection of the mill. All accounts agree that the mines present the best showing of any in the county, there being about 1,000 tons of ore on the dumps, and enough in sight or so well opened that a hundred men could be put to breaking down ore whenever it is wanted. There have been a series of delays in getting in the machinery for the mill, which is reported as being still at Mojave, but the carpenters have received some timbers, and are going ahead with their work.

MARIPOSA.

CONCENTRATORS.—*Gazette*, Jan. 13: The Yosemite mill at No. 9 mine has again started up, after an interval of three weeks for repairs and the addition of 12 Frue ore concentrators, chlorination works are also being erected. The Mt. Gaines mine, in connection with the No. 9, has again resumed the usual din and bustle of vigorous business activity. The Quartz mountain mine, under the management of Messrs. Webber & Rodgers, is temporarily closed.

MONO.

BODIE CON.—*Free Press*, Jan. 16: During the past week 135.6 tons of ore were hauled to the mill and 135.7 tons were crushed. The average assay value of the pulp was \$48.45 per ton, that from the sacked ore being \$271.84, and the average value of the tailings was \$7.03. The bullion shipment was valued at \$5,723.23. There were 201 carloads of ore hoisted from the mine, of which amount 27 carloads were from the stopes at the 740 level of the shaft, and 64 loads were extracted from the workings between the 640 and 780 levels. Stopes will soon be opened from the 770 shaft level, where the vein has been reached by the short east crosscut showing good ore.

STANDARD CON.—There were extracted and sent to the mills last week 1,427 tons of ore, and \$25,572.60 were shipped to the company in San Francisco. The east crosscut, 1,000 level, was advanced during the week 12 ft; total length 1,109 ft. The rock in the face is hard and shows no change. The east crosscut from the south drift is in 202 ft; progress since last report 18 ft.

BULWER CON.—The south drift from the west crosscut, 600 level, has been extended since last report 10 ft; total length 366 ft. There is no change in the appearance of the ground cut through, which is hard and shows some quartz.

BODIE TUNNEL.—The mill is kept supplied with ore and the stopes look well. There is no change to report in the formation.

NEVADA.

THE MASCOETTE.—*Grass Valley Union*, Jan. 13: Work on the Mascotte quartz claim is progressing under the superintendence of Mr. George Murphy. A perpendicular prospect shaft has been put down to the ledge, some 20 ft, where both the foot and hanging walls are found smooth and regular, and the vein having a pitch of 74 degrees. The shaft is being carried down from this point on the pitch of the vein to water level, which is 4 by 8 ft inside of timbers and lined throughout with planking, and will be divided into two compartments, one for car track and the other for pump and ladder way. The shaft is also to be carried up to the surface on the same incline, and timbered in the same manner, and then, when the hoisting works, which are in process of construction are completed, the work of sinking the shaft below water level will be vigorously prosecuted. The probabilities are that the Mascotte will open out into a strong vein, as the space between the walls containing the ledge and ledge matter is between 4 and 5 ft.

MORE OF THE LITTLE BONANZA.—*Nevada Transcript*, Jan. 13: H. B. Nichols and E. B. Russell's quartz mine is still panning out well. In the last three days \$700 worth of gold has been taken out. The drift yields \$100 worth of gold to the foot and gives about \$1.75 to the pan. The shaft is down to water level and in the hard rock below the water gold can be seen. We were shown a lump of gold taken out to-day which is worth \$25 by weight.

PLUMAS.

CRESCENT MINE.—*Greenville Bulletin*, Jan. 10: On Monday evening a clean-up was made at the Crescent mine after a 4 days' run with 4 stamps, and the result was \$4,000 worth of bullion. The ore body opens out better every day. The Taylor-Plumas mill is almost completed; little more than laying the water-pipe remains to be done. The Green Mountain mills are both running steadily, and have been yielding better during the past week or two. The 3 mines are located in the form of a triangle, the Crescent being down on the flat at the foot of the mountain, the Taylor-Plumas about 250 yards northwest and the Green Mountain about 500 yards southwest, and up the mountain. The main lode is consequently tapped at a greater depth in the Crescent mine than in either of the others, and as it is the uniform experience there that the ore is richer as depth increases, so doubtless it will be with both of the other mines. The present workings of the Green Mountain at their greatest depth are several hundred ft above even the surface ground of the Crescent mine.

SPANISH PEAK.—*Plumas National*, Jan. 13: From Mr. M. Matheson, who has been in the lower country for some months, and who called on us the other day, we learn that there is good reason to believe that capitalists will in the early spring take hold of the Monte Christo property, and push the prospecting tunnel ahead. There are many good miners who yet believe that there is a magnificent gravel mine in that mountain, and if Mr. M. is correct the fact will yet be demonstrated. We hope the work will be resumed, for we have never lost faith in the property, and believe that it only needs muscle and money to show it up among the best drift mines in the State.

INDIAN VALLEY.—The new air compressor has been received at the Indian Valley mine; the whole machinery belonging to it is on the ground. Mr. Manson is expected back from San Francisco this week, and when he comes he will at once proceed to erect the machine and get it to work.

SHASTA.

THE AFTERTHOUGHT MINE.—*Redding Independent*, Jan. 13: A. J. Loomis, of Red Bluff, who is interested in the Afterthought mine at Furnaceville, in this county, tells the *Enterprise* that under the management of J. O. Stewart the mine is likely to be a complete success. Mr. Stewart has a new pro-

cess of extracting copper and silver from the dirt, and it is working to the entire satisfaction of the superintendent and owners. He is taking out about 1,000 lbs of pure copper daily, and expects to take out a ton daily as soon as two more stamps are put up in working order. The copper taken out has been from dirt around the mine that was considered valueless, or nearly so, by those who worked the mine several months since. If the refuse dirt is yielding so satisfactorily, then the company may reasonably expect good results when the best of pay ore is handled.

SIERFA.

BONDED.—*Mountain Messenger*, Jan. 13: The Phoenix quartz mine, at Sierra City, has been bonded to Eastern capitalists, and they are proceeding with its development.

A report reaches us that Jack Billings has struck a large deposit of rich gravel in his diggings at Sebastopol. Our informant was of the opinion that he had reached the main tunnel.

TRINITY.

LUCKY ESCAPE.—*Trinity Journal*, Jan. 13: Bartlett & Evans have a new 600-foot bedrock tunnel in their mine at Red Hill, through which water was running last Saturday, when it suddenly dammed up at the head. Three men, Pat Lawton, John Dacy and John Lumly went up through the tunnel to see what was the matter, and about the time they got to the dam it broke and the rush of water washed two of them the entire length of the tunnel and safely deposited them on the dump, the third man clinging to the side of the drift and avoiding the free ride. Fortunately none of the men were injured aside from some slight bruises.

A LITTLE WATER.—The storm of last week started the water in the mines and that was about all. More storm is needed at once, as there is so little snow on the hills to keep up the supply.

TUOLUMNE.

THE PATTERSON MINE.—*Tuolumne Independent*, Jan. 13: Supt. W. F. Drake is making a splendid property of the Patterson mine, and the company, which is made up of strong and willing men, have been lavish in their expenditure to carry out the well-framed plans of the master workman. So pleased with the results of his stewardship, the Trustees East have wired that he had been elected superintendent with sole charge. The new mill is running 20 stamps. From an experienced miner employed, we understand that everything is looking splendid—the deeper they sink the better the ore. A new chute of ore has been struck in the shaft which shows gold freely—vein 6 ft and gold better quality. The No. 3 levels just opened are in good ore of higher grade. Had a splendid clean-up last month—and returns are better each month by almost double. By like good management other mines now lying idle in this county could also be worked to good profit.

NEVADA.

WASHOE DISTRICT.

OPHIR.—*Enterprise*, Jan. 13: The broken spur-wheel will be repaired by to-morrow. The accident has delayed no work at the Union shaft, nor did it interfere with the pump, and the water has been handled without difficulty by apparatus other than that affected by the breaking of the wheel. The sump in the joint Mexican winze below the 300 level will be completed to-day.

SIERRA NEVADA.—On the 2700 level the east crosscut is making good progress. It will be in ground in about two weeks in which a change may be looked for. On the 2900 level the joint Union Con. east crosscut is being pushed forward as rapidly as possible.

UNION SHAFT.—All the new pumps have been lowered to the levels on which they are to be set up. As soon as all is in readiness for the change, the old pumps will be lifted from their foundations and the new ones put in their places, beginning with the lowest, that on the 2700 level. The breaking of the spur-wheel at the Ophir caused no delay, nor will it cause any.

UNION CON.—The joint Sierra Nevada east crosscut on the 2900 level is making good headway. Being now well out from the station, blasting may be pushed. The joint Mexican east crosscut on the 2900 level is passing into ground showing more quartz than was first seen.

YELLOW JACKET.—The old upper levels continue to yield about 60 tons of ore per day. On the Sagebrush level there is found to be an immense area of ore that would yield about \$9 per ton, but at the present cost of extraction and reduction nothing can be done with this. In addition to the work done in taking out ore now prospecting is being done, and deposits of ore now hidden may be brought to light.

MEXICAN.—The joint Ophir winze has been sunk 12 ft below the 300 level for a sump. This sump will be completed to-day. A station will now be opened at the 300 level, and a crosscut started east in the vein. The bottom of the winze shows an increase of quartz.

CHOLLAR.—The south drift has passed into mineral-bearing quartz, giving low assays. The drift is fast nearing the Potosi line. At present the trend of the lode is toward the east, which causes the drift to cut into it deeper than heretofore. The chances are good for finding something of value down about the north line of the Potosi.

ALTA.—The drain drift to connect with the Suro tunnel on the 1030 level is being advanced at a rapid rate. It is now out over 250 ft. The completion of this drift will give new life and capacity to the pumps, as it will at once relieve them of the great strain of the dead weight of a column of water 1,030 ft in height.

SAVAGE.—The joint Hale & Norcross north drift on the 2600 level is being pushed along at the rate of about 30 ft per week in ground of promising appearance, though rather soft for rapid progress, as close timbering is required. Quartz feeders giving low assays are beginning to be cut.

CON. VIRGINIA.—The south drift on the 2700 level is being advanced at the usual speed. The face continues to show quartz giving low assays. All the hoisting of men and rock is now being done at the C. and C. shaft, pending the changing of the pumps at the Union shaft.

CROWN POINT.—Large quantities of ore still being taken out. This is of a very low grade—averaging but about \$11 per ton—but its extraction gives employment to a great many men, who would otherwise be idle, and keeps the mine and all connected with it in good repair.

SCORPION.—The usual progress is making in the main east drift on the 500 level. The material is still vein matter, which looks about the same from day to day. The drift already shows the lode to be of immense width at this point.

GOULD AND CURRY.—The west crosscut on the 2500 level is being rushed along at the rate of about 60 ft per week. It is in vein porphyry streaked with quartz and seams with clay.

HALE AND NORCROSS.—The joint Savage north drift on the 2600 level is progressing at the rate of about 30 ft per week. The material is a mixture of quartz, clay and porphyry.

BULLION DISTRICT.

COPPER.—*Elko County Free Press*, Jan. 13: At Bullion, which is also known as Railroad district, they are still pegging away, and with no inconsiderable success. The Blue Bell Company a short time since completed a run of 500 tons of carbonate ore in their furnace. There is no longer room for doubting that the old Empire City mining company's property has changed hands, and now belongs to Mr. Riley and friends. They are said to have a large quantity of galena ore in sight. At the Sweepstake mine a fine breast of ore can be seen, which assays from 25 to 40 per cent. copper and carries \$80 a ton in silver.

COMET DISTRICT.

NEW DISCOVERY.—*Pioche Record*: Great tales are told on the streets of a wonderful discovery recently made by Jim Burrows in what he calls Comet district. This new find is located on the west side of the Highland range, about 10 miles due west of the Floral Springs. Several samples of rich ore, which assays in the hundreds, have been brought to town, and if it is anything like the description that disinterested parties have given us, they getting their information from Burrows, indeed Jim is a most fortunate man, and he has more rich ore on top of the ground than the trains of Vanderbilt and Gould would be able to haul for the next 50 years. There is nothing like being lucky.

EUREKA DISTRICT.

GEDDES & BERTRAND.—*Eureka Sentinel*, Jan. 12: A representative of the *Sentinel* had an interview yesterday with Mr. Atchison, foreman of the Geddes & Bertrand mine. He tells us that they have just made a shipment of 18 bars of bullion, 980 fine, valued at \$1,000 each approximately, to the reduction works of Selby & Co., San Francisco. The mill is reducing about 54 tons daily, the average assay value of which is 28 ozs, for which they got, in December, \$7.13 1/2 per ounce, or about \$32 per ton. This, Mr. Atchison says, is about the average yield at present, \$36,000 per month of 30 days. The total expense of running mill and mine is \$8,000 per month, leaving thus a net profit of \$28,000 for the month.

PEAVINE DISTRICT.

BULLION.—*Virginia Enterprise*, Jan. 9: The Antelope mine, in Peavine district, has just shipped 5 bars of bullion to Boston. The mine is being worked by Boston folks.

TUSCARORA DISTRICT.

BULLION SHIPMENT.—*Times-Review*, Jan. 9: Navajo made its regular bullion shipment of 8 bars this morning, aggregating \$15,182.50.

NORTH BELLE ISLE.—Everything is looking well in this mine. The boiler has been repaired, and this morning the work of sinking was resumed, and the men returned to the places which they occupied before suspension.

WHITEWASH.—On the hills near the Navajo is found a very curious deposit, apparently hundreds of feet in extent. It is a white substance resembling marl, but when mixed with water makes a superior article of whitewash. It hardens immediately, is pure white, leaves a good coating, and will not rub off like ordinary wash made of lime. It makes a beautiful finish. An experiment with the material was tried on the ceiling of Cockbin's barber shop.

AT THE GRAND PRIZE.—Since Friday last workmen have been engaged in putting in place the plunger at the bottom of the Grand Prize shaft, which job was completed and all connections made at 4 o'clock this morning, and the pump set in motion. Although the pump is running only 7 strokes per minute, at the time of our going to press it had emptied the shaft of some 60 or 70 ft of water which accumulated therein, showing that it was equal to any emergency. The work of hoisting waste, of which there is a great accumulation in the drifts, will now be resumed, and the work of exploration vigorously pushed forward. The west drift from the 700 level, now in some 52 ft, and which was suspended from fear of encountering a greater flow of water, will now be driven ahead. The saving in expense of running the Prize, now that the steam pump has been discarded, will be \$200 per day, or about \$6,000 per month.

ARIZONA.

SMELTER.—*Phoenix Herald*, Jan. 12: By the 1st of April the mining interests of Phoenix will receive an impetus by the erection of a good-sized smelter on one of the copper mines of Castle Creek, and the erection of a 40-stamp mill on one of the Cave Creek mines. The latter, we are credibly informed, will be put up during next month, or at least the business of putting it up will begin then. The energetic work being done in both the sections of country named will ere long bring yet other mills and smelters into this region of country, where they will find almost limitless work and ample remuneration.

NOTES.—*Tombstone Epitaph*, Jan. 10: The early morning of the 1st inst. saw many persons on the hills in this district relocating claims. Many had their pains for nothing, but we hear of one fortunate man who had the hardihood to relocate a well-known claim and cleaned up a few days later with \$1,500 for his night's work. We hear of some copper mines having lately been discovered in the vicinity of Co-chise's stronghold which promise well. We have also seen some very fine looking rock from a claim near Morris' wood ranch. The last year, however, has been a quiet one in this district. Most of the claim owners simply kept up their assessment work, and others have relocated their properties to hold on for another term. Col. Hafford, with his usual luck, is the owner of a claim from which he has lately taken some samples which assay 20 per cent. copper and \$64 in silver. His claim is situated 10 miles southeast of Picacho, in Pima county. The Copper Queen broke a shaft of one of their blower engines, and consequently had to shut down one of their smelters. Ben. Williams, the superintendent, is in town, and by his energy has done much to repair the damages reported. The Pinal Con. mining company, at Butte

City, Pinal county, under the able management of Aaron Mason, superintendent, is now shipping bullion. The smelter works splendidly. The Santa Catarina mine, Pima county, has developed a rich vein of copper ore. At the depth of 40 ft a vein of 6 inches of almost pure metallic copper was struck. There is over 1,000 tons of from 18 to 20 per cent. in sight. Blue Monday and Enlie show signs of returning and replenished vitality.

IDAHO.

THE WOLFTOSE LEDGE STRUCK IN DEPTH.—*Wood River Times*, Jan. 13: Another rich strike is reported in the Wolltose mine, on Deer creek, in the lower drift. Last Monday the ledge came in strong, and from 2 to 3 ft in width—of rich carbonate and galena ore. The dip of the vein, which has heretofore been to the west, has changed to the east, and the ledge now pitches into the hill. The miners are going after it lively. This new strike is under the original discovery, and is very encouraging as indicating the continuance of the ore chimney in depth.

A RECENT STRIKE.—Capt. Hledsoe, superintendent of the Penobscot mine, was in town yesterday, and reported that ore was struck last Saturday in tunnel No. 3, the lowest workings in the property, and at a depth of 150 ft from the surface. The heading had been in ledge matter for over 100 ft, cutting through fine looking vein matter, but early Saturday morning ore appeared in the breast. It proved to be only a stratum 3 inches thick, but this was followed by two other strata of like thickness, and the mere finding of ore at that depth is held to be an exceedingly promising indication. The Penobscot is controlled by Judge V. Stamps Anderson, of this city, and is located about 6 miles from Hailey, on the same ledge as the Minnie Moore.

MONTANA.

MINE SOLD.—*Inter Mountain*, Jan. 13: About 3 months ago Green Campbell, of Utah, and C. N. Larabee, of this city, bonded of W. J. McNamara and James Larkin a two-thirds interest in the Mountain View mine for \$20,000. The remaining third was owned by C. N. Larabee. Since that time the property has been actively explored, and the showing of the mine so rapidly improved that its purchase was decided upon long before the bond expired. On Saturday last the necessary deeds were drawn up, transferring a two-thirds interest to Messrs. Campbell and Larabee. The mine adjoins the St. Lawrence on the northeast, and if it should prove to be an extension of that magnificent ledge, it is worth 10 times the amount paid for it. The mine is developed by a shaft 200 ft deep, from the bottom of which considerable exploration has been conducted. It is exclusively a copper mine. . . . The Colorado smelter is reducing about 50 tons of ore per diem.

The Clear Grit continues to develop handsomely in the 220 west level. The Alice company is paying to-day. About \$50,000 will be disbursed. Seventy-five mineral locations have been recorded during the past week in this district. Mechanics are still at work on the mammoth machinery at the Anaconda, which will not start up for 10 days. The Stedfeldt furnaces at the Lexington mill are giving excellent satisfaction, the percentage of chlorination being uniformly high.

NEW MEXICO.

PERCHA DISTRICT.—*New Mexico Mining World*, Jan. 3: The Carpenter district, on the opposite side of the range from Percha, is being prospected, and some good finds reported. Almost pure silver is still being taken out of the Solitaire mine, in the Percha district. Unless the ore runs out, this mine will prove to be one of the richest ever discovered. The town of Kingston is very quiet, notwithstanding the great activity in the mines. Considerable development work is being done all through the Percha district, and the people of Kingston are expecting a big boom in the early spring. The 10-stamp mill at Hillsboro is doing a big business. It is crushing about 20 tons of ore per day. About 3 carloads of ore are shipped every week. The Animas mining district, 15 miles northeast of Kingston, is reporting some very good strikes. The Bullion mine, near Kingston, has a true fissure vein, the ore running about \$250 to the ton. Kingston, named from the Iron King mine, and its surroundings, mines and prospects, is situated on the strike of the grand mineral belt of the Membras mountains, or Black Range, and gives great promise of being a camp of continuous productiveness. The first rich mineral in the district was found on the Solitaire mine last August by Jack Shadden, the discoverer of the famous Robinson mine in Colorado. The claim had been located, in 1881, by H. J. Wilson. Shadden, not knowing of a prior location, took possession of the mine and bonded it to Tabor and Wurtzback for \$100,000.

UTAH.

BULLION.—*Salt Lake Tribune*: During the week ending January 6th there were shipped from Salt Lake 19 cars of lead, 458,212 lbs; 2 cars copper matte, 40,700 lbs, and 51 cars bullion, 1,161,497 lbs, making a grand total of 72 cars, aggregating 1,660,409 lbs. This is a good beginning for the first week in the new year.

CRESCENT.—Mr. Daily, superintendent of the Crescent mines, reports the daily average output from the property at about 30 tons. This ore is hauled to the sampling mill on runners. There is no more snow at Rebellion mine than there was one month ago.

HIDDEN TREASURE.—Capt. Wilder is running a long and deep tunnel for the benefit of the Hidden Treasure property in Dry canyon. This was a great producer for several years. Work on the new smelters of the Mammoth is being pushed energetically.

SALES.—More mining sales are pending in Utah at present than at any time in the past two years. This is by reason of the big output of ore and bullion in 1882, and the favorable mining outlook in nearly every district in the Territory.

TINTIC is now one of the liveliest mining districts in Utah. A great deal of money is being spent in development, and the output of ore is larger than ever before.

SEVERAL old and supposed to be worked out mining camps in Nevada have lately come to the front. Conspicuous among them are Tuscarora, Austin, Conio, Jefferson and Ophir Canyon, which are now exceeding their palmy days in bullion production.

Denver Exposition—No. 23.

Editorial Correspondence.
Pima County, Arizona.

Pima county is said to be the oldest mining locality in the United States. The early Jesuit missionaries and their immediate associates were engaged in mining operations at quite a number of different points in this county something like 250 years ago. From the many old shafts and tunnels which are yet to be seen, it is evident that mining was carried on then quite extensively. It was within the present boundaries of this county that the famous "Planchas de Plata"—"planks of silver"—were found, which are said to have yielded five tons of pure metal. It lies directly west of and adjoining Cochise county. Its valleys contain quite an extent of fine grazing land, while its mountains are rich in minerals.

The construction of the Southern Pacific railroad has imparted a wonderful impetus to the mining and other industries of this county, as it has, indeed, to the entire Territory, and especially to the southern tier of counties, through which it passes. The county is divided into 13 mining districts, and millions of dollars have already been invested in opening their numerous mines. Harshaw district contains one of the leading mines of the Territory—the Hermosa. The ore is chloride, and is worked by a 20-stamp mill. The yield to date is about \$700,000. It has been opened to a depth of over 300 ft. The Trench, one of the old Spanish mines, is opened to the depth of 400 ft. with steam hoisting works. The Hardshell, Alta, Blue Nose, American and Independent are among the mines of this district.

Washington Camp district contains many large veins of low grade ore, but generally carrying a large per centage of lead. The Belmont is one of the oldest locations in the district. It has quite a heavy vein of carbonate ore. The "Old Mowry" mine is one of the most noted of the district. It was worked before the war by Lient. Mowry, and gave employment to some 400 men, mostly Mexicans. Large smelting works were erected, but the building and machinery were all destroyed by the Apaches. The main shaft is down 350 feet. The mine is now owned by parties in Tucson. There are mines enough in this district to make it one of the leading districts in the Territory.

Tyndall district boasts of quite a number of mines with promising prospects, but it is claimed that the district has suffered much from bad management and unscrupulous speculators.

Arivaca district contains a 10-stamp mill, with steam hoisting works upon the Con. Arizona. This district also contains the famous Cerro Colorado mine, which is said to have yielded some two millions of dollars before the war. The works were all destroyed by the Apaches, and have not been since rebuilt. The mine is now owned by the Arivaca M. and M. Co. To the west of Arivaca is the Baboquivari range, which is said to contain several valuable mines worked by the early Spaniards.

Oro Blanco district contains several valuable mines, yielding chiefly carbonates and free milling ores—gold and silver. The Warsaw mine has produced some \$30,000, and has a 10-stamp mill with roaster. The Yellow Jacket also has a 10-stamp mill. The Empire district, some twenty miles east of Tucson and just south of the line of the Southern Pacific railroad, has recently become somewhat prominent by the discovery of the "Total Wreck," said to be an immense body of chloride ore, 50 feet wide. A large amount of ore has been raised, and reduction works are soon to be or are already in process of erection. We have no room for mention of other prominent mines and districts.

Copper.

Pima county also contains several valuable mines of copper—veins are reported 50 feet in width, with very rich ores of carbonates, oxides and glance. A 30-ton smelter has just been erected by the Huachilacha Company.

Yavapai County

Is the largest in area in the Territory. It also maintains a prominent position as a bullion producer. It is the leading county in the production of gold, which occurs both in placers and in ledges. Silver and copper are also found in many localities in almost all the various forms of their ores. The first mining discoveries in the county were of gold, and made at Weaver Creek, at which point mining has been successfully carried on up to the present time. Peck district, some thirty miles southeast of Prescott, has produced a large amount of bullion. The Peck mine, in this district, has produced over \$1,200,000 since its discovery in 1875. Ore of extraordinary richness is sometimes met with in this mine, which has been opened to a depth of over 400 feet. The ore is worked by a 10-stamp mill and roasting furnace.

The Tiger, a silver mine in Tiger district, near the above, is one of the largest veins in the Territory—70 feet between walls. It is opened to a depth of over 300 feet, and is equipped with steam hoisting works and a 10-stamp mill. It has thus far produced \$250,000. It is a true fissure vein, and quite a number of extensions have been located. Several valuable mines have been opened in the Bradshaw basin, in this district, yielding gold chiefly. A 10-stamp mill is located there.

In the Tip-top district, 50 miles southeast of Prescott, there are a great number of promising mines, several of which are paying regularly.

A 10-stamp mill and roaster have been erected for working the Tip-top mine, the principal one in the district, which has already produced over \$1,000,000. There are one or two other mills in the district erected for custom work.

The Hasayampa district is located about 10 miles south of Prescott, in a heavily timbered, well watered region, which is considered one of the most delightful summer resorts of the Territory. The creek from which the district takes its name has been worked for gold ever since the first settlement of Arizona by the people of the United States. It is essentially a gold producing district. But as depth is reached in the mines the gold gradually decreases and a large percentage of silver comes in, much as on the Comstock lode, at Virginia City, Nevada. The Senator has been quite extensively worked, and has thus far yielded about \$175,000. It has a 10-stamp mill. The Crook, near by, has produced some \$50,000. There are at least 30 or 40 other mines in this district well worthy of mention.

Walker district, seven miles east of Prescott, embraces the head waters of Lynx creek, the richest gold-producing stream yet discovered in the Territory. Upwards of \$1,000,000 have been already taken from it since its discovery, in 1863. The district abounds in valuable mines of both gold and silver. The Turkey Creek and Big Bag, Grover Creek and Cherry Creek districts, all in the immediate vicinity of Prescott, are well watered and well wooded localities, containing rich mines, the most of which are as yet but slightly developed, but many of which in the near future bid fair to become valuable. The attention of Eastern capitalists is now being attracted to this neighborhood.

Weaver district is one of the oldest mining localities in the Territory. From a small depression upon the summit of Rich Hill \$500,000 in coarse gold was taken, mostly lying upon the bed-rock near the surface. About the same amount was taken from the three or four gulches running down from this locality—\$1,000,000 in all. A 300-ft. wide gold-bearing quartz vein lies near this locality, upon which there are about 200,000,000 tons of quartz in sight within 100 ft. from the surface. Good, and sometimes very rich, milling rock is assorted from this immense quartz deposit. Upon the Model mine, in the same district, a Huntington mill has been erected. Of the Tonto Basin Silver Mountain, Walnut Grove, and other districts, we have no space for mention. The Silver Belt silver mine, 16 miles east of Prescott, has a smelting furnace of seven tons capacity which has already turned out over \$100,000 in silver. The Wickenburg and Zika mines, in Black Canyon, are each worked by arrastras to good profit.

Yavapai county is also rich in copper ores, which are found in all parts of the county. The only mines, however, which have been thoroughly opened are those in the Black Hills, about 20 miles northeast of Prescott. An Eastern company has recently purchased the Eureka, and has made arrangements to erect reduction works upon it.

Pinal County—Silver King.

Pinal county has become quite well known through the wonderful developments at the famous Silver King mine, which may now be considered, whether in size of the vein, richness and variety of its ores, or in the aggregate of the bullion yield, one of the great mines of the world. We have already spoken of the rich and elegant exhibit which this mine made at Denver. The croppings of the Silver King were found upon a low conical hill near the center of a basin surrounded by spurs of the Pinal Mountains. This mine was discovered by a discharged soldier, who, with his associates, after working it for two years, taking out several thousand dollars, sold it to some San Francisco and Oakland capitalists, who still continue to work it. The vein matter is chiefly quartz, and the ore a sulphuret carrying native silver, copper glance, antimony and other combinations. It forms one of the richest bodies of silver ore ever discovered. The main shaft is now down over 600 ft., with five levels—shaft and levels everywhere showing fine ore, which in places is proven by crosscuts to be 80 ft. wide. The ore is worked by a 20-stamp mill, at Pinal, five miles distant from the mine. There are also roasting and concentration works. The ores are treated by the lixiviation process. The extensions both upon the north and south are being developed by the aid of steam hoisting works. The Belcher, in the same district, is a promising mine, with a 10-stamp mill. The proprietors of the Eureka, upon the same ledge, were about making arrangements a year ago to put up a mill. A custom mill has already been put up, or soon will be, at the mouth of the San Pedro, to work several prominent mines in that neighborhood.

Copper is also found in this county, and a 30-ton smelter is in successful operation on the Gila river, near Florence, treating ores from a group of mines in the foothills some five miles distant.

Gila County.

This is said to be one of the most thoroughly mineralized counties in the Territory, containing gold, silver, copper, lead, coal and iron. An expedition of nearly 300 men, led by the Governor, penetrated into this county, then an Apache stronghold, in 1871, in search for placer gold. In their unsuccessful search for that they overlooked the really rich mines of silver and copper which they passed over. The Indians for a long time guarded well the treasures which they know were hidden within their mountain homes; but the strong arm of the white man finally prevailed, and the now fa-

mons Globe district, in this county, was opened up to industry and commerce. Hundreds, if not thousands, of tons of rich ore has been freighted to San Francisco for treatment from this district. A large number of mines are now opened. Two 10-stamp mills and one 5-stamp mill are now in operation in the district, respectively on the Miami, the Champion and the Townsend mines.

The Richmond Basin, in this county, has become famous for the silver nuggets which have been picked up there—over \$80,000 have been picked up from the surface in the vicinity of a single camp, near which is now the McMorris mine, which has yielded to date about \$625,000. The mine is provided with steam hoisting works and a 10-stamp mill. There are several other valuable mines in the same neighborhood.

The McMillenville group of mines, 20 miles north of Globe, are located upon an immense fissure, traceable for twelve miles across the county, one of which—the Stonewall—is well known in this city from the rich specimens which it has produced. It is now provided with a 5-stamp mill and steam hoisting works. It has yielded, to the present time, considerably over \$300,000.

Copper mining in this county promises to become an important business. It contains some of the richest in the territory. The Globe, the first opened, is now consolidated with several others, upon which three furnaces have been erected, with a united capacity of 100 tons per day. The bullion is shipped to Baltimore, and pays from two to three hundred dollars per ton in silver. The daily bullion production is about four tons. Gen. A. McDowell, of Chicago, is one of the principal owners and the earliest promoter of this group of mines; he is reaping a rich return from his investment.

Mohave County.

This county is located on the central portion of the eastern border of the Territory. It is a mountainous and exceeding rich and abundant in mineral bearing veins. Almost every mountain range appears to be seamed with mines rich in silver, gold and copper. Much of the county abounds with wood and water. Nearly all the ore obtained is picked rock, which is shipped to San Francisco at great expense for treatment. There are but two or three small mills in the county; but as soon as the Atlantic and Pacific railroad makes its connection through from Albuquerque, in New Mexico, to the Southern Pacific, at Mohave, a new impetus will be given to the mines of this county. The same advantage will also accrue to all the mineral range of country through the entire length of the northern portion of the Territory. The famous McCracken lode, which extends for miles across the country, is located in this county, and with the opening of the railroad will begin, with other neighboring mines, to send large amounts of bullion to this market. The McCracken Consolidated Company has already expended \$200,000 in improvements, and realized over \$800,000 in silver from its mines. The company is now running a 20-stamp and a 10-stamp mill.

Yuma County

Occupies the southwestern corner of the Territory. It has long been known to be rich in gold placers, and is comparatively convenient of access from the Southern Pacific railroad, which passes directly through the county. Mining was first commenced here in 1862, and in 1863 fully 2,000 miners were working the placers in the foot hills near La Paz, about 70 miles north of Yuma, who soon took out a million and a half of gold. The mines of Castle Dome district, 20 miles north of Yuma, were discovered in 1863 by Prof. Wm. P. Blake, a well known geologist, for many years a resident of this city. There is a large group of mines in this district which although yielding a low grade of ore, are nevertheless among the most profitable in the Territory. It is estimated that the district has yielded fully \$2,000,000. Silver district is also one of the leading camps of the county. It is convenient of access, and contains some of the heaviest ore bodies in the Territory. The Red Cloud, a New York company, has, perhaps, the largest development. It has yielded over \$100,000. Its ores are treated at its own works—a 20-ton furnace. The Ellsworth district is a promising locality—has many promising mines. The Oro mine has a five-stamp mill. Messrs. Thomas Eells and Richards, of this city, are opening a very promising mine in this district.

Maricopa County.

East of Yuma, though generally considered an agricultural county, has many promising mines. The well-known Vulture mine is located in this county. This mine has produced \$3,000,000. It has been opened only to a depth of 400 ft. It is a very heavy mine, showing a width at one place of fully 100 ft. The ore is now reduced in an 80-stamp mill, at a cost of only \$2.50 per ton. More stamps will soon be added, and the bullion product be increased. The Golden Star, on Cave creek, is a promising mine, and has a 10-stamp mill. A 5-stamp custom mill is also in operation about four miles from Phoenix, run by water from the Grand canal.

Graham County

Is the youngest born of the Territory, but the richness, extent and variety of its minerals is fast giving it great prominence as a copper and bullion producing locality. Graham can probably show some of the most productive copper mines in the United States. The famous Longfellow mines are located on the San Francisco river, in this county. Before the opening of the South-

ern Pacific railroad, copper matte was shipped from these mines 700 miles by wagons to the nearest railroad. But notwithstanding the enormous cost of the transportation, the mines were worked at a profit. This mine appears to be a regular mountain of ore; neither tunnel nor drift has yet found a vein wall. The property is worked as a quarry, rather than a mine. It belongs to a company which keeps its business to itself. Hence very little information can be gained as to its yield. Report fixes it at about three and one-half tons of matte per day. The amount, whatever it may be, will soon be materially increased by a proposed increase of the reduction facilities. The mines will soon have direct railroad communication by a branch with the Southern Pacific railroad.

Extensive Placers.

The placer mines on the San Francisco river in that country are very extensive and undoubtedly rich. A Boston company has recently purchased 1,000 acres of placer ground there, and are making preparations to work it on a large scale. These gravel beds have been thoroughly prospected and show good pay gravel everywhere. Fifteen miles of piping have been laid, and hydraulic appliances will soon be put up for working this ground in a thorough and economical manner.

Bullion Yield of Arizona.

No truer test of the richness of the Arizona mines can be found than the steadily increasing volume of bullion shipments from that Territory. The yield has probably increased three fold since the Southern Pacific railroad has been constructed through the so then mineral field of the Territory. A like increase may reasonably be expected to follow the completion of the Atlantic and Pacific, which is now nearly completed through the northern portion of the State. And when a complete railroad system for the Territory is constructed by branches from and connections with the two great trunk lines; no one need be surprised to see Arizona suddenly step to the very front rank as the largest bullion producing Territory in the Union.

The yield of the Territory for 1881, as reported by Wells, Fargo & Co., was \$4,000,000; but this did not include the raw ores, concentrations and large amount of placer gold which annually finds its way out by private hands. The Mint report for 1881 gives the yield for that year as \$8,440,775. This estimate does not include the copper product, which may be set down at fully \$1,500,000, nor the ores shipped out of the Territory. In view of the rapid rate of bullion increase, it may be safe to estimate the yield for the year 1882 at fully \$10,000,000.

[Since the above was in type we have received the following, which is probably as reliable as anything we can get short of actual official reports: "The value of the copper produced in Arizona for the year 1882 was \$2,945,284.40, being 17,201,586 pounds. The gold and silver yield of the Territory was \$10,257,089.88. The Tucson Star believes there was produced \$1,500,000 worth of copper not reported, and therefore not included above."]

This is certainly a good showing for a Territory where total shipment seven years ago amounted to only \$109,083. Probably no mining region can make a better show for the capital invested than Arizona. Capital there has been less reckless than almost anywhere else, and there is probably no country where the character and value of the mines can be more readily determined or with greater certainty.

Quartz Mills in Arizona.

The number of quartz mills and stamps in Arizona is given in the last Mint Report as follows:

County.	No. Mills.	No. Stamps.
Cochise.....	9	145

Useful Hints.

We clip from a late number of the Prescott Miner the following useful hints which may not be out of place in this connection: "As a general thing in Arizona, ores found upon the surface are free milling, and so long as the ore remains such in going down upon the various mines which have been worked, good results were achieved, but so soon as water level is struck and sulphurets appear, the ordinary machinery in use fails to save the metal, and suspension of operations is necessary. In every instance, without a single exception, assays show the sulphuret ores to be the richer, hence the only thing necessary to make mining a success in all this section is the proper machinery for the treatment of rebellious ores. Experienced men to operate the machinery necessary for properly treating base ores is also very essential. Mining, like other things, must be dealt with intelligently, and because one run upon certain ore fails to pay it does not necessarily follow that another run will. Good management and favorable circumstances have much to do with the treatment of ores."

W. B. EWER.

MONEY VALUE OF SCIENCE.—The Signal Service office estimates that ships containing at least \$13,000,000 of property, besides many lives, were saved from running into the disastrous cyclone during the month of November last, by the warning it gave. The money thus saved in this one storm would pay the expense of the Service for 10 years.

THE ENGINEER.

THE CANADIAN PACIFIC TO BE COMPLETED IN 1887.—Mr. Collingwood Schreiber, chief engineer of Government railways, who was recently on a tour of inspection over the Canadian Pacific railway, has been interviewed by a reporter of the *St. John, N. B., Sun* on the progress of work on the great national highway with the following interesting results:

"Calendar station," said Mr. Schreiber, with the air of a man who knows just what an interviewer wants and exactly what he doesn't require, "is the western terminus of the old extension of the Canadian Central. The track is laid from Calendar station for thirty miles westward, and the road is graded for about twenty miles in advance of that. From this point, fifty miles west of Calendar, to the river there is a gap, and the surveyors are now at work locating the line. Between the river and Prince Arthur's Landing a long stretch of rough, hilly, rocky country intervenes. Here the grading is progressing very rapidly, and probably five or ten miles of track are in position. Calendar station to Prince Arthur's Landing comprises what is called the eastern section, which is 650 miles or so in length from the crossing of the Saskatchewan. Surveys are in progress over the Rockies to Kauloops. The eastern end of the work to Emory's Bar, 127 miles is being constructed."

CANAL CONSTRUCTION IN EUROPE. Among the many canals projected on the continent of Europe is one to connect the Danube and the Elbe, one from Cologne to Antwerp, and a third to connect Brussels and Louvain with the sea, likewise by way of Antwerp. The Danube-Elbe project is an important one, for the proposed canal would be 138 miles long, and would, it is estimated, cost \$29,000,000. The depth of the water in the canal would be six and a half feet, and the width of the canal bed forty-eight feet. The value of each of these canals obviously would be very great; and that connecting Cologne and Antwerp would have an immense influence in still further developing the resources of Belgium. The prosperity of Cologne would be greatly enhanced, a consummation most devoutly to be wished, if it should carry with it some diminution of the famous "seventy stinks, all well defined, and several stenches," of the city of the Eleven Thousand Virgins.

THE CHANNEL TUNNEL.—According to reports from Paris, the suspension of the boring of the Channel tunnel is regarded in that city as a lamentable error of judgment on the part of the Government and people of England. The French company, meantime, are going forward diligently with the boring on this side. M. Raoul Duval, the Director of the Calais and Dover railway, and a strong partisan of the scheme, has just been to Calais for the purpose of inspecting the works, which are progressing perfectly under the direction of M. Breton, the engineer who is conducting this great undertaking. The gallery on the French side is now about 1,600 ft. in length, with a square diameter of a little over six and a half feet, and it already extends to a distance of over 100 ft. under the sea. The Beaumont machine, which is worked by compressed air, will be used until the gallery measures about 5,000 ft. in height.

ELECTRIC NAVIGATION.—Prof. S. P. Thompson lately gave a description of the trial trip of the *Electricity*, a launch propelled by a screw actuated by an electro-motor, the current for which was supplied by storage batteries of the Sellen-Volekmar type. The launch is 26 feet long, about 5 feet wide, and draws about 2 feet of water, the propeller being about 22 inches in diameter. She carries 45 storage batteries, each about 10 inches cube, said to be capable of supplying 4 horse-power for 6 hours. The accumulators have an electro-motive force of 96 volts, and during the run the current through each machine was steadily maintained at 24 amperes. Prof. Thompson reports the speed of the vessel to have been about 8 knots an hour against the tide, while the return journey from London Bridge to Millwall (distance not stated) was made in 24 minutes.

SAWDUST IN THE UPPER MISSISSIPPI.—The statement was made some time ago on what seemed to be good authority, that the Upper Mississippi was gradually becoming filled with sawdust, and that it was or soon would be detrimental to navigation. *Wood and Iron* says that a joint committee of prominent business men and steamboatmen of St. Paul and Minneapolis have been making an investigation of this matter, and found no sawdust accumulating in the main channel, and think the accumulation in the eddies and shallows will prove an advantage, instead of, as was at one time feared, a serious impediment to navigation; that is, by lodging on the wing-bars and shallows it serves the purpose of protecting them from the washing of the current, by which the sand was removed and deposited in the main channel.

A NOVEL BRIDGE.—A patent has recently been taken out for a bridge, which is so constructed that it will be raised off its foundations by high water, and at the same time can be used for crossing. To each end of the bridge aprons are hinged, which connect at one end with the foundations at the road levels and with the bridge at the other end, and afford practicable ascent to and descent from the bridge while it is floating above the foundations.

USEFUL INFORMATION.

Chinese Mode of Manufacturing Sheet Lead.

The making of sheet lead for the lining of tea chests, etc., is a somewhat important industry of Hongkong. It is made principally in sundry establishments to the westward. On entering one, the workmen will be seen with shears busily employed in cutting out the sheets of lead into the required sizes and shapes. The shears are simply a large pair of scissors, firmly fixed to a solid block of wood two feet in height. The lower blade of the shears terminates in a square piece of iron, instead of being pointed, as is the upper blade. The sheets of lead will also be observed to be of small size and somewhat irregular in shape, and this arises from the method of manufacture, as will subsequently be seen. Going further into the shop will be seen an iron pan raised 12 inches or so above the ground and carefully finished off.

Beneath this iron pan is a furnace, and at the side of the pan next the wall is the flue communicating with it. In this pan the lead is melted, and when judged to be hot enough, the workmen take two of the large, square paving tiles, which may be seen almost anywhere in the colony, and these are then smoothly and carefully covered with several layers of unsized paper. Having placed these two tiles before him, one above the other, the workman raises the upper tile with his left hand, and taking a ladle of the proper size in his right, he dips it in the melted lead and then pours its contents on the upper tile and quickly presses the lead out in the form of a sheet. The paper being a bad conductor of heat, the lead does not solidify immediately it leaves the ladle, and, by long practice, the workmen always ladle out exactly the same quantity of lead; the sheets made vary but little in size or thickness.

"Crackle" Glass.

An ingenious process for producing glass with an iced or crackled surface, suitable for many decorative purposes, has been invented in France by Bay. The product appears in the form of sheets or panes, one side of which is smooth and glossy like common window glass, while the other is rough and filled with innumerable crevices, giving it the frozen or crackled appearance so much admired for many decorative purposes. The peculiar crackled surface is obtained by covering the surface of the sheet on the table with a thick coating of some cross-grained flux mixed to form a paste, or with a coating of some more easily fusible glass, and then subjecting it to the action of a strong fire, either open or in a muffle. As soon as the coating is fused, and the table is red hot, it is withdrawn and rapidly cooled. The superficial layer of flux separates itself in this operation from the underlying glass surface, and leaves behind the evidence of its attachment to the same, in the form of numberless irregularities, scales, irregular crystal forms, etc., giving the glass surface the peculiar appearance to which the above name has been given. The rapid cooling of the glass may be facilitated with the aid of a stream of cold air, or by continuously projecting a fine spray of cold water upon it. By protecting certain portions of the glass surface from contact with the flux, with the use of a template of any ornamental or other desired form, these portions will retain their ordinary appearance, and will show the form of the design very strongly outlined beside the crackled surface. In this manner letters, arabesques and other patterns, in white or colored glass, can be produced with great ease and fine effect.

LUMINOUS PAINT.—The color of the light of luminous paint is generally white, or at first a little bluish or yellowish white. A Dresden firm now produces various paints—pure white, blue, red, green, violet and gray, so that the objects which become luminous at night may have a pleasing appearance by day. This paint is fast becoming utilized for various purposes. The last we noticed is that of a railway carriage painted inside, and intended to be placed on one of the trains between London and Rotherhithe, via the Thames tunnel. Although only one-half of the available space of the carriage is painted, the phosphorescent light is quite sufficient to enable the passengers to distinguish small objects when passing through the tunnel; and, moreover, the light is powerful enough to enable a person to read the indication of an ordinary watch. It is probable that the railway companies will be enabled to effect a considerable saving in gas and oil by using the phosphorescent paint.

WATER PROOF PAPER.—By plunging a sheet of paper into an ammoniacal solution of copper for an instant, then passing it between the cylinders and drying it, it is rendered entirely impermeable to water, and may even be boiled without disintegrating. Two, three or any number of sheets rolled together become permanently adherent, and form a material having the strength of wood. By the interposition of cloth or any kind of fiber between the layers the strength is greatly increased.

NEW PAVING MATERIAL.—An experiment is to be made in New Orleans to adopt mosquito wood, a native of Texas, very durable and nearly as hard as iron, for street paving purposes. It is so abundant that the cost of cutting and transporting it will be very light.

The bicycle is steadily widening its field of usefulness. The experiment of its employment by letter carriers for the delivery and collection of mail matter seems to be a success, and it is likely that the next thing will be its utilization for the delivery of newspapers in suburban localities. In the West it is already coming into use for newspaper delivery. The *Cincinnati Gazette* is served regularly to subscribers in the town of Greenville, Ohio, by carriers mounted upon bicycles.

WHITE JAPAN FOR REFLECTORS.—A white paint for lamp reflectors which has a fine porcelain finish and needs no heating is made as follows: Mix pure white zinc (dry) with sufficient soluble glass (silicate of soda) to be easily applied with a brush. Apply one coat and dry by artificial heat, if convenient; then apply a second heavy coat, and dry either in an oven at from 150 to 200 F., or at ordinary temperature.

SOLIDIFYING PETROLEUM.—We have already in this column mentioned the fact that some French chemists had succeeded in so solidifying petroleum that it could be readily handled in solid cubes. We now learn that this solidification is effected by adding to distilled petroleum 25 per cent. of the purified juice of plants belonging to the family of the euphorbiaceae. Petroleum solidified burns like tallow or paraffine.

IRON AND WOOD MAY BE JOINED WITH THE FOLLOWING COMPOSITION: Fine Russian isinglass is dissolved in strong acetic acid (pyroglucous acid) until the consistence of a strong, firm glue is obtained.

A NEW glass, transparent and more brilliant than common crystal, but containing no silica, potash, soda, lime, or borax, has been invented by a chemist in Vienna. It can be cut and polished, and when fused adheres to iron, bronze and zinc.

ANNEXATION EXTRAORDINARY.—A few weeks ago, during a heavy storm, the Rio Grande river suddenly changed its course by cutting through a bend near Camargo, and thus placed several acres of inhabited territory in Mexico within the legal limit of the United States.

UTILIZING PYRITES.—The manufacture of sulphuric acid from pyrites has recently been commenced at Nashville, Tenn., and at Atlanta, Ga.

GOOD HEALTH.

"Weight" in the Stomach.

I frequently meet a case of indigestion, the most marked feature of which is what the patient calls "weight in the stomach." Sometimes it is spoken of as a pressure, and again as stricture, but the most common word is *weight*. Sometimes the patient will say, "It seems to me I have a stone or a mass of iron;" and one lady said, the other day, "I have an iron wedge in my stomach." Generally these sufferers attribute the sensation to the weight of food. A clergyman said, "I suppose my stomach has become sensitive to pressure, and the food pressing upon the surface which has become so tender produces this sensation of weight." This explanation is entirely at fault. Instead of being produced by the presence of a heavy mass in the stomach, in its most intense and unbearable forms, I have found that it does not appear in connection with a full meal, but is much more likely to come on after eating a few mouthfuls of cracker or fine flour bread, or a single hot biscuit. The patient may have ground it with his teeth with the greatest ease, but, soon after swallowing, this sensation of weight appears. More frequently, however, there seems to be no connection whatever with the presence of food in the stomach. The sensation is not produced so much by what is in the stomach as by certain conditions of the walls of the stomach itself; in brief, it is produced by congestion of the walls of the organ. Accompanying this congestion there is generally an adhesive mucus poured out which sticks to the inner coat. I may add that this sensation of weight is nearly always a little to the right of the pit of the stomach, and that it is found that the congestion and adhesive mucus, which seem to stand in the relation of cause to this sensation, are found at the right or pyloric extremity of the stomach.

This sensation of weight is not relieved by stimulus. If it was produced by a load of food pressing upon the weakened walls of the stomach, a glass of whisky or wine would afford at least a temporary relief, whereas it is found that the employment of alcoholic drinks only increases the trouble. Indeed, drunkards suffer more intensely from this sensation of "weight in the stomach" than any other class of dyspeptics.

The most striking relief, for the time being, is obtained from hot fomentations over the pit of the stomach. A mustard poultice applied over the stomach is very effectual.—*Dr. W. Lewis.*

THE CONDITIONS OF HEALTH.—In order to have good health, the following conditions are imperative: 1. Pure air. 2. Pure and nutritious food. 3. Proper exercise. 4. Undisturbed sleep. 5. Regularity. 6. Temperance in all things. 7. Pleasant and active mental, moral and social conditions. 8. Right bodily positions. 9. Cleanliness. 10. Sunlight.—*Herald of Health.*

CAUSES OF SICKNESS.—A reporter visited Mr. Brewer's Academy, at San Mateo, at the time of the death of Ashley Oldham, of Gilroy, one of the pupils. As there were some cases of diphtheria in the school, the eye of the reporter was led to notice the superabundant shade of trees and shrubs which shut out the sunlight from the premises and caused mwholesome vapors from the irrigated grounds to produce diseased germs. In his judgment, this was the cause of sickness at that pleasantly-situated institution. A few days since we were driving on the San Juan road and noticed the surroundings of the residence of the Allen family, in which there has recently been one fatal case of quinsy and a reported case or two of diphtheria. On the south side of the house, a few feet distant from it, is a coral where scores of cows stand at milking time, and where they leave their fecal matter to dry in the sun and poison the air. This foul, disease-breeding air is wafted by the southern breeze into the house, where the sick try to live off its effects by the aid of medicine and the daily visits of the doctor, which extend over weeks and months. The suffering inmates want pure air. Move them, and the house with them, to the fine elevation some few hundred yards to the west, and in a short time they will be able to "throw physic to the dogs."—*Gilroy Advocate.*

CARBOLIC ACID FOR DIPHTHERIA.—In a communication to the *Chicago Medical Journal*, Dr. McGill describes a method of treating diphtheria, from which he has secured far better results than from any other. He uses an ordinary hose, from two to five feet long and about one inch in diameter. One end of this is placed over the spout of a common tea kettle, into which has been put half a gallon of water and half an ounce of carbolic acid; the kettle is then placed on the stove over a good fire, and when the water reaches the boiling point the end of the hose is carried under a blanket thrown over the patient's head. The room must be closed. In a short time the patient will perspire freely. If persevered in at short intervals, the breathing becomes softer, and presently, after a succession of quick, expulsive efforts, the patient throws off a coat or tube of false membrane. The acid vapor seems to prevent the reformation of exudations. Alcohol and sulphate of quinine are used in conjunction with the acid for the supporting properties.

ANÆSTHETIC BULLETS.—A German chemist has invented a new kind of bullet, which, he urges, will, if brought into general use, greatly diminish, if not altogether remove, the horrors of war. The bullet is of a brittle substance, breaking directly as it comes in contact with the object at which it is aimed. It contains a powerful anæsthetic, producing instantaneously complete insensibility, lasting for twelve hours, which, except that the action of the heart continues, is not to be distinguished from death. A battle field where these bullets are used will in a short time be apparently covered with dead bodies, but in reality merely with the prostrate forms of soldiers reduced for the time being to a state of unconsciousness. While in this condition they may, the German chemist points out, be carefully packed in ambulance wagons and carried off as prisoners. Whole cities may in a like manner be reduced to helplessness by means of shells charged with the same compound. The anæsthetic bullet is also strongly recommended to the burglar and to the householder, no risk of hanging being involved by its use.

A NEW THEORY OF CONSUMPTION.—Consumption has hitherto been regarded as a disease of the lungs, which cannot be reached directly except by inhalation, and the value of that form of medication is problematical. A new theory of the disease, called the Salsbury theory, makes it one of unhealthy alimentation. According to this view, it is the fermenting of food in the stomach, which furnishes to the circulation noxious material that affects the lungs on reaching those organs. Granting the truth of the theory, we shall have to consider consumption as curable. All that needs to be done is to use only such food as will not ferment in the stomach, and to clean out that organ occasionally by a judicious use of warm water, with simple tonics before meals to aid the digestive process. A weak solution of ferrie per sulphate is recommended for inhalation to check hemorrhage in the severe stage of the disease. The idea is well worthy the attention of the many who are supposed to be in the initial stages of consumption. It would be an inestimable boon if it be the means of saving them, to say nothing of the many others whose cases are otherwise hopeless.—*Chicago Tribune.*

HOUSE PLANTS AND CONSUMPTION.—Professor Crudeli, of Rome, points out in the *Practitioner* that the keeping of plants in ill-ventilated rooms may cause malarious infections even in regions where malaria is unknown. Professor Eichwald, of St. Petersburg, reports the case of a lady who was attacked by true intermittent fever while living in a room containing plants, yet after the removal of the flower pots a cure without a relapse was effected. The mwholesome influence is said to be due, not to the plants, but to the damp earth in which they grow.

FOOD FOR CONSUMPTIVE PATIENTS.—Milk powder, mixed with powder of beef, is reported as having been used successfully by Dr. Dujardin-Beaumont in keeping up the strength of consumptive patients. For use both articles are dissolved in ordinary milk, and the stomach is said to be very tolerant of the mixture.

Passing Events.

There is very little news to report from the mining point of view. The news from Alaska, which we give in another column, telling of the discovery of placer mines on the Yukon river, is important; still it has been known that there was gold on the Yukon some time since, but the expedition now there is the first one which has made systematic work of it. They had a steamer and plenty of provisions. In a few years much more attention will be given to Alaska mining matters than is now the case.

The State Legislature is in session, but has done nothing so far of special interest to the miners or mechanics of the coast.

At a meeting of the Pacific Exchange Association after the adjournment of the Stock Board, the building and property of the Association was disposed of to an unknown bidder, supposed to be Charles Crocker, represented by C. H. Reynolds, a real estate dealer. The amount was \$81,000, which is said to be a great sacrifice. The land alone is said to have cost \$192,000, and the buildings nearly \$40,000 more. The Board will continue to occupy the building, renting of the purchaser.

The Navajo and Independence mines, at Tuscarora, paid \$40,000 to miners, teamsters and merchants this week on December account.

Expenditures on Placer Claims.

A very unexpected decision has been announced by the Supreme Court of this State in the matter of assessment work on mining claims, declaring that annual expenditures are required on placer claims the same as on lodes.

This decision is entirely contrary to what has generally been supposed to be the law of the subject. Section 2,324 of the Revised Statutes provides that, "On each claim located after the 10th day of May, 1872, and until a patent has been issued therefor, not less than \$100 worth of labor shall be performed or improvements made during each year."

Heretofore all the constructions of the law by the Interior Department, the Commissioner of the General Land Office, or the courts, have been to the effect that only lode claims were subject to the annual expenditure, placer claims being omitted.

In the case in point, however, is a very important decision, overthrowing all previous rulings. The case is that of Carney vs. the Arizona Mining Co., of Sierra county. The case was originally tried in the Superior Court of that county, and in substance was as follows: Carney and others located a tract of placer mining ground at the head of Jim Crow canyon, marked their boundaries properly, ran a tunnel several hundred feet in length and did other work. Some years afterwards the Arizona company located a large portion of the same ground, ran a long tunnel and applied for a patent. The original locators filed an adverse claim. The case came to trial, and the Arizona company set up that the boundaries were not, at the time they relocated, so marked as to be readily traceable, and that for more than a year previous the yearly expenditure had not been made. The plaintiff proved properly marked boundaries, and the Court held that no yearly expenditure was required by United States law on placer claims. Decision was rendered in favor of plaintiffs, and defendants appealed. It is the appealed case just decided which reverses the generally accepted tenor of the law. The appellant relied principally on the failure to do annual work, and this view of the case has been accepted and the decision of the Superior Court reversed, judgment being given for the defendants.

There is one point about this case that will make it a leading one. There were no local laws involved, as there were none in force in the district, and the decision is therefore one of general application referring to the general mining laws of the United States. Under this decision \$100 will have to be spent in labor or improvements each year on placer claims of 20 acres, or \$800 on each 160 acres, a fact miners will do well to remember. In view of the importance of this decision, we give it in full:

DEPARTMENT TWO.

[Filed December 21, 1882.]

CARNEY

VS.

THE ARIZONA GOLD MINING COMPANY.

No. 8,639.

In December, 1876, plaintiffs and their grantors located a series of placer mining claims, which claims contained about 100 acres. Work was done said claims until October, 1878, since which day the Court finds "plaintiffs did no work or made any improvements on their claim, of any value whatever, for the purpose of working, prospecting or improving their claims." The Court also finds that during the absence of the plaintiffs and their grantors, defendant's predecessors in interest, August 7, 1880, entered upon a portion of said lands, and located by Government subdivisions 81 72-100 acres of the mining ground previously located by plaintiff's predecessors in interest, in compliance with the laws of Congress, and proceeded to work by tunnel and shaft within their location lines, but outside of the boundaries of plaintiff's claims, and had, at the time of commencing this suit, expended \$6,000 in such work.

The substantial question involved in this controversy is whether the laws of Congress, requiring a certain amount of annual work to be done by persons claiming to hold until patent issued, apply as well to the class of claims known as placer claims as to the class known as lode or vein claims. The Act of Congress of May 10, 1872 (Sec. 2234, U. S. Rev. Stat.), requires that "on each claim located after the 10th day of May, 1872; and until a patent has been issued therefor, not less than \$100 worth of labor shall be performed or improvements made during each year;" and upon a failure to perform such work, the claim shall be open to relocation in the same manner as if no location had ever been made, provided that the original locators or their representatives have not resumed work before such relocation. Granting that from a close reading of the various sections of the act, from Section

2,319 to 2,328, Revised Statutes, it might appear that the clauses of Section 2,324, above referred to, were intended to apply only to claims upon lodes or veins, we are of opinion that Section 2,329 removes any doubt, and that the performance of annual work is required as well upon the one class of claims as upon the other. In Section 2,329 it is declared that claims usually called placers, including all forms of deposit, excepting veins of quartz or other rock, in place, shall be subject to entry and patent, under like circumstances and conditions and upon similar proceedings, as are provided for vein or lode locations. We think the effect of this section is to declare that the circumstances and conditions under which vein or lode claims may be entered and patented shall be likewise applicable to placer claims; that as a location of a vein or lode claim may be kept alive for the purpose of entry and patent only by the performance of the requisite amount of annual work, so a placer claim must be kept alive for the same purpose in the same manner. The Act of January 2, 1880 (21 Stat. at Large, 61), amending Section 2,324, Revised Statutes, is in harmony with this view, in speaking, as it does, of "the vein, lode, ledge or deposit sought to be patented."

Judgment reversed and cause remanded, with instructions to render judgment for defendant as to the lands within its location.

We concur:

MORRISON, C. J.
SHARPSTEIN, J.

MYRICK, J.

The Consolidated Virginia Mine.

The famous Consolidated Virginia mine on the Comstock, that paid for months consecutively million dollar dividends, and made colossal fortunes for a few men, only produced in bullion last year the pitiful sum of \$1,631.48. Yet the mine has been constantly worked. The work has been confined to opening out and partially prospecting the 2,500 and 2,700 levels, in the accomplishment of which there have been hoisted 10,090 tons of waste rock. On the 1,500, 1,650, 1,750 and 1,950 levels the drifts connecting with the old stopes still remain bulkheaded, it not being considered prudent as yet to attempt opening the old stopes. On the 2,300 level the drift run by the Best and Belcher Co. from the Gould and Curry and Best and Belcher joint shaft was connected in May last, and forms a valuable connection between that shaft and the C. and C. shaft. No further work has been done on this level except keeping open the various drifts, and connecting winzes necessary for ventilation.

Work will soon be commenced to continue the winze from the 2,500 level, now sunk 218 feet, down to the 2,900 level. The 2,700 level was reached last February by the joint winze sunk from the 2,500 level. A station was cut out and a joint lateral east drift was started in March. This joint east drift has been extended 450 feet and connected with the main south lateral drift run through the lateral ground in June last, which carries the natural ventilation down to this level and forms a base for future operations in depth.

Mr. W. H. Patton in his annual report concludes as follows: Our work the past year has demonstrated the fact that the Comstock lode in our lower levels continues to show great strength of formation, and the cutting of seams of quartz, giving assays, in the various drifts on the 2,500 and 2,700 levels, shows that it is mineralized, with a probability of finding ore deposits of value when the lower levels are fully opened. By the judicious use of the diamond drill I have been able to avoid, or control, the influx of larger quantities of water than our pumping machinery could handle. The sum of \$196,213 has been spent this year on the C. and C. shaft.

A PRIZE FOR MINE LAMPS.—A gentleman of Manchester, England, Mr. Ellis Lever, has offered a prize of £500 for the most perfect portable lamp for mining purposes. A competent committee is to investigate by actual test all the lamps brought forward for competition. Here is a chance for inventors in this country who think they know what a mine lamp is and how to make one. It is expected that the lamp shall be an electric one. It is curious that an objection like the following should come from one of the English mining papers: "Exclusive of candles used in some few mines, we believe it may be assumed that at the various coal mines in the kingdom there are now something like 600,000 lamps in use, and were these to be replaced by those lighted by electricity, this would involve a loss or expenditure of an enormous sum of money."

Getting Rid of Non-Paying Partners.

The mining laws of the United States provide that upon the failure of anyone of several co-owners to contribute his proportion of the annual expenditures required, the co-owners who have performed the labor or made the improvements may, at the expiration of the year, give the delinquent co-owner personal notice in writing, or notice by publication in the newspaper published nearest the claim, for at least once a week for 90 days, and if at the expiration of 90 days after such notice in writing or by publication the delinquent should fail or refuse to contribute his proportion, his interest in the claim becomes the property of his co-owners who have made the required expenditures.

It must be remembered that the party who contributes his portion of the required expenditures can retain his interest. If a party fails to contribute his proportion of the actual expenditures upon a mining claim, the remedy lies in the courts. The U. S. mining laws only provide for failure to expend the proper proportion of the annual expenditures required by those laws.

In the first place, when the partners have done their share, and one miner has done his, he who has done the work records an affidavit like the following, which is *prima facie* evidence of the performance of such labor:

Proof of Labor.

—of — County of —, ss.
Before me the subscriber personally appeared —, who being duly sworn says that at least — dollars' worth of labor or improvements were performed or made upon (here describe claim), situated in — mining district, — county, — of —, during the year ending —, 188—. Such expenditure was made by or at the expense of —, owners of said claim for the purpose of holding said claim.
[Jurat.] — (Signature.)

NOTE.—The record of an affidavit like the above is *prima facie* evidence of the performance of such labor.

Then a notice of forfeiture should be sent to the delinquent, and published in the local paper. At the expiration of 180 days this notice should be recorded, with the affidavit of the newspaper publisher that the same was published for 90 days, together with the affidavit of the party signing the notice to the effect that one or more of the partners or co-owners named in the published notice have not paid their share of the expenditure. This completes the record title. This notice of forfeiture is as follows:

Notice of Forfeiture.

— County, —, 188—. To — (names of all parties who have record title to any portion of the mine). You are hereby notified that I have expended — dollars in labor and improvements upon the — lode (describe the claim), as will appear by certificate filed —, 188—, in the office of the Recorder of said county (or district), in order to hold said premises under the provisions of Sec. 2,324 Revised Statutes of the United States, being the amount required to hold the same for the year ending —, 188—. And if within ninety days from the service of this notice (or within ninety days after this notice by publication), you fail or refuse to contribute your proportion of such expenditure as a co-owner, your interest in said claim will become the property of the subscriber under said Section 2324.
— (Signature.)

The affidavit of failure to contribute, referred to above, is in the following form:

Affidavit of Failure to Contribute.

— of —, County of —, ss.
—, being duly sworn, deposes and says that for the year ending —, 188—, he expended at least — dollars in labor and improvements upon the — lode (or — placer claim) (here describe the claim), to hold the same under the laws of the United States and of this — (district, Territory, or State); that due notice thereof was personally served upon —, co-owners, on the — day of —, 188—, (or was duly published in the —, as appears from the affidavit of the publisher thereof), and that — (of the said) co-owners have failed or refused to contribute their share of said expenditures within the time required by law.

Subscribed and sworn to before me this — day of —, 188—.

THE NEW YORK COMMERCIAL construes the election of Henry Villard, John W. Ellis and Fred Billings, Directors of the New York, Lake Shore and Buffalo railroad, as meaning a separate trans-continental road beginning at New York and ending at Puget Sound.

The Keeley Motor.

It will be recollected that the stockholders who have for several years past been furnishing Mr. Keeley with the means to pursue his investigations and construct his promised new motor recently became dissatisfied with his continuous delays and calls for more money, and commenced a suit to compel him either to initiate proceedings for obtaining a patent or divulge to them the precise nature of his discovery. This he has ever steadfastly refused to do, except in general terms; but after the suit was commenced, a proposition to stop the same was agreed upon, on condition that Mr. Keeley would disclose everything in full to a third party—an expert. The expert was mutually agreed upon in the person of William Boeckel, who has entered into close intimacy with Keeley, thoroughly investigated the whole matter, as he claims, and reported his full confidence in the actuality and practical value of the discovery, with the assertion that “both men of science and practical engineering skill alike would stand amazed to-day if they realized what Keeley has already accomplished.” The stockholders have expressed their fullest confidence in the report of the expert, and have also received from Mr. Keeley a note, in which the following sentence occurs:

“I am glad that all past misunderstanding between us has been removed, and have no doubt that the present friendly feeling and confidence will be maintained uninterruptedly. At your request, and with the aid of Mr. Boeckel, and of counsel, I have prepared a caveat for my generator, which has been forwarded to the Patent Office.”

Boeckel says he fully understands the motor, Keeley says he is ready, and the stockholders say they are satisfied. This is certainly a highly gratifying state of affairs all around.

The Keeley motor excitement commenced in 1874, and has been kept up for the past eight years with a degree of success highly creditable to the ingenuity of the inventor. He has now, practically, about two years longer in which to continue his experiments, worry his stockholders and practice upon the credulity of human nature in general, if such is his purpose.

But to be serious, it is much safer to admit the possibility of Keeley's alleged discovery than to denounce it as a humbug. So many wonderful things have been accomplished within the last fifty years that any man is regarded as somewhat reckless who ventures to pronounce anything impossible which it is impossible to prove so. The ocean steamship, the railroad, the telegraph, the telephone and the photophone were each and all once regarded, by good engineers and scientists of undoubted standing, to be just as impossible as the Keeley motor is now pronounced to be.

The Keeley motor comes under the head of the seemingly impossible, simply from the fact that it is based upon a secret law of nature, which, it is alleged, has been discovered by Keeley. No man can prove, or, in light of the past, safely say there is no such law. The safest thing to do is to still wait and hope for another two years' time, when it is barely possible “men of science and practical engineers” may once more stand amazed at the actual accomplishment of the seemingly impossible.

What Keeley Claims

As his discovery is the fact that water in its natural state is capable of being, by vibratory action, disintegrated so that its molecular structure is broken up, and there is evolved therefrom a permanent expansive gas, or “elastic medium,” or force, which result is produced by mechanical action with force capable of exerting an expansive energy of at least 25,000 pounds per square inch. In support of the reasonableness of such a possibility, Mr. Boeckel, in his argument, calls attention to a work recently published by Mr. Woodbury, member of the American Society of Mechanical Engineers, relating chiefly to the construction of mills, in which he recorded many interesting phenomena observed by him as to the vibration of mill structures. Among other examples, Mr. Woodbury mentions numerous instances where large stone structures have been thrown into rapid and is some cases dangerous vibration through the influence of a musical tone caused by a body of falling water some distance from the structure so vibrated. It is to be understood that the result so caused is not attributable to the concussion caused by the falling water, but is a phenomenon of a wholly different character, and which neither the increase nor the decrease

of the volume of water is capable of producing, if thereby a key-note not in sympathy with that of the mill structure is produced.

Mr. B. refers to other well-known similar instances, and adds that Mr. Keeley's inquiries have been conducted in this direction, and that his investigations and experiments have carried him far beyond the laboratory experiments of Crookes, Tyndall and other scientific investigators, until he has succeeded in exciting, harnessing and utilizing the subtle force which, to them, has been only a subject of scientific wonder.

When the great energy of this new gas or elastic medium, or other source of energy, was first discovered, Mr. Keeley thought to utilize it in a manner similar to the utilization of steam, but he soon made the still further discovery that this new substance, or source of energy, possessed properties wholly unlike those of any other substance hitherto known, for which reason he was compelled to occupy much time

VERTICAL SECTION OF THE ENGLISH SLAG HEARTH.

in studying its properties and in devising some new way to produce and utilize the enormous energy which could be thereby developed. As a result he constructed what he called his “vibratory engine,” the details of which as a developer are well known to all the parties immediately interested in the invention.

But his great work, as claimed by the scientific expert, has been to devise some mechanical device whereby the power evolved by the proper mechanical vibration of water may be taken off and employed for useful work. This work, the expert claims, has been successfully accomplished, and three several engines constructed, the first of which was a measurable success, but the degree of success has been vastly augmented in succession by the second and third attempts. Mr. Keeley is still sanguine of further improvement in this direction,

HORIZONTAL SECTION OF THE ENGLISH SLAG HEARTH.

but is willing and has already filed his caveat for the progress he has thus far made, and will proceed to prepare his final papers within the two years still allowed him by the patent laws.

He considers his work as about completed, and is now constructing a fourth engine of 500 horse power, which will soon be completed and in full operation. The purpose is also announced of so bringing the matter to the attention of the Philadelphia Railroad Company as to have the first practical trial made upon their road between Philadelphia and New York. The stockholders and the public are assured that the line of experiment is now fully passed, and nothing is left to be done but the completion of the mechanical work upon the machine.

If there is a hitherto unknown law of nature which Mr. Keeley has discovered, the public are impatient to receive the proof, after which they will be ready to give Mr. Keeley all due honors for his discovery.

THE Congressional Committee on Ways and Means struck from the free list borax and boracic acid on the representations of the borax producers of the Pacific Coast, where deposits have been discovered, but need no protection. A rate of ten cents a pound was recommended for borax. This will interest those owning the borax works near Columbus, Esmeralda county. The duty will put thousands of dollars into their pockets. Borax only sells for ten cents a pound here, so the duty is full value.

Gold in Alaska.

In June last we gave an account in the MINING AND SCIENTIFIC PRESS of two parties having started for Alaska on mining expeditions. One of these parties, which went up on a sailing vessel, took a small stern-wheel steamer for the purpose of prospecting along the Yukon river. It was known that there were gold diggings several hundred miles from the mouth of the river, and the party intended to make a thorough exploration. Information has now been received that Schieffelin and his party, with the little steamer, carrying one-half of the three-years' supplies, ascended the Yukon 1,500 miles and established camp at the mouth of the Tananana. The boat was then sent back to St. Michaels for the remainder of the supplies, and Schieffelin went on a prospecting tour. Shortly after the boat left on the return voyage he made discovery in gravel washings of sufficient importance to justify the detail of a courier to

make the long and perilous journey overland to Sitka in order to convey the news rapidly to his brother, a capitalist residing in Philadelphia. The courier reached Sitka safely and dispatched the letter, which came to San Francisco on the last steamer, and is now on the way to Philadelphia by rail. It is reported that the washings in the gravel beds averaged \$1.50 per pan, and that in some instances \$10 per pan was produced.

The Yukon is an immense river, but is little navigated. There is a steamer running there which makes about two trips a year, but most of the navigation is by canoes. The river is frozen over until June, and as for paddling up stream when it is open, it is pretty hard work. Individual miners without much money would find the country rather an unpleasant one to go into. From all accounts

travel on foot is extremely difficult, owing to swamps, moss-covered surface and the dense timbers. If the information received is authentic, there will no doubt be many persons venturing the trip up the Yukon; but for the ordinary prospector, with small means, it will be a risky business.

Ex-Collector William Gouverneur Morris, of Alaska, who has just come back from there, and is on his way to Washington, in the course of an interview on Alaskan affairs, incidentally mentions the mining interests. The formation of the lodes, said he, is unlike any other known to the geological world, being entirely glacial in character. You will find a lode at the base of a mountain 3,000 or 4,000 ft. high, and you can trace it distinctly up the side, and on reaching the top you will find there an auriferous deposit, made by the moraine of the glacier, from 15 to 20 ft. deep. This is claimed by the surface diggers as placer claims, and for the last two seasons they have been successfully worked, to the detriment of the quartz claimants. About \$250,000 was taken out last season near Juneau and on Douglas island alone.

There being no courts whatever in the country, no law and no vestige or form of government whatever save that administered by the captain of a man-of-war and the Collector of Customs, it follows that those rival rights are as yet undetermined. No injunction can issue to restrain the placer diggers from pursuing

their vocation, and the quartz owners have so far restricted themselves to a policy of non-intervention, and have gone on sinking shafts and running tunnels to determine the value of their lodes. The work done is of a satisfactory character, and will justify further expenditure. Several mining companies have been formed in this city, backed up by men of capital, of which Wm. T. Coleman is one of the prime movers.

On Douglas island, opposite Juneau, is a series of mines as large as the whole Comstock lode. The opening of one of these lodes has so far demonstrated the value of the property that it is understood that the owners contemplate soon to erect a 100-stamp mill. The ore, though of low grade, is free milling and easily worked. In fact, said he, there is the largest body of ore in sight in the known world. The attention of Eastern capitalists has been directed to the island and a party of scientific and wealthy men will visit Alaska in the spring to examine this property. Though the interests of the placer and quartz miners clashed, and though there was no semblance of law, the miners were well behaved and orderly. Some time ago Commander Merriman visited the island in the U. S. ship *Adams*, in the interest of the preservation of the public peace, and induced both parties to come to an understanding by which the placer miners used the water during the day and the quartz miners during the night. But in his opinion this state of affairs could not last forever, because the development of the lodes will attract adventurous spirits who can't be easily controlled. It is, therefore, incumbent upon Congress at this session, if possible, to establish a court of justice, if nothing else, for that portion of Alaska. This all the miners are in favor of, and until this is granted it is no treasonable to be expected that capitalists will go to any very great extent in investing their means in that country.

English Slag Hearth Furnace.

The bottom of the furnace hearth, which slopes forwards and downwards, is formed of a cast-iron bed plate, *c*. In front of the hearth is a cast-iron tank or trough, *e*, known as the lead trough, into which the metal is run from the hearth, while in front of this again is another trough or slag pot, *f*, for the collection of the slag as it flows over from the surface of the metal in the lead trough.

In working this hearth it is first slagged out, or freed from any adhering slag left from the previous shift, and any badly corroded spots in the lining are repaired with clay, after which the bottom, or bed plate of the hearth, is covered with a layer of ashes, or small cinders, to a depth of from five to six inches, and made to slope like the bed plate from back to front, but leaving a space between its upper surface and the lower edge of the fore-stone, which space is stopped with clay, with the exception of an opening, or tap-hole, through which a quantity of the slag flows during the smelting campaign. A quantity of fuel, usually peat, is placed upon the hearth thus prepared, and ignited by the addition of a little burning coal, when the blast is turned on, and a quantity of coke is then thrown into the hearth. As the smelting proceeds, the reduced lead and the accompanying slag descend to the bottom, where the ashes, placed upon the bed plate of the furnace, serve as a kind of filter, through which the lead percolates and passes out from the front edge of the hearth into the tank, *e*, placed in front for its reception, and in the bottom of which is usually introduced a layer of cinders for further separating the metal from any slag passing out along with it. The lead flows from the lead trough, *e*, into a lead pot, heated by its own fire, and from which the metal is ladled into ingots, while the slag, passing from the hearth along with the lead, accumulates in the lead trough, which it overflows, and passes to the slag pot, *f*, already spoken of, and in which it collects; but the greater portion of the slag produced during the process of smelting passes out from the furnace through an opening made by a bar in the clay stopping.

At the end of the shift, when materials have ceased to be added to the furnace, and lead likewise ceased to flow from the hearth, the clay stopping is broken down, and the slaggy matter remaining on the hearth is raked forward and collected for addition as slag-hearth browse at the commencement of the next shift. The shift often lasts about eight hours, of which about six hours are employed in the smelting and two hours in cleansing out and preparing the hearth for the next shift. The lead produced in this hearth, and which is known as “slag lead,” is always hard and impure, from the presence of sulphur, antimony, copper and iron,

Nevada's Salvation.

Under the above heading the Carson *Tribune* publishes some sensible ideas in relation to the benefits Western Nevada will receive from the construction of the Carson and Colorado railroad, now being pushed southward. We copy the following extract as being to the point: But for the energy of the few men who risked their personal means in the construction of the road referred to, a fearfully dark prospect would be before us at this time, for the chances are strongly against any development on the Comstock that will be of general benefit, and but for the C. & C. the ledges south would have still lain dormant, if not undiscovered, and so we claim that the people of Western Nevada have much reason to be thankful that such men as control the narrow-gauge possessed not only the means but the energy to enter into such a speculation as the C. & C. R. R. The taxes of Esmeralda county will be greatly augmented, and so in Lyon county; hundreds of people will obtain employment, towns are building up along the line of the road; farmers will be benefited, mills will be erected and better than all for Carson, the number of employees in the machine shops of the V. & T. R. R. will be kept up if not increased, and so we say that the thanks of the whole community of the several counties through which the railroad passes, and of the Carson people, are due to the projectors and building of this very important railroad, for without doubt it will prove the salvation of Western Nevada.

The Esmeralda *Herald*, in speaking of the road, says: The Carson and Colorado railroad is already of great benefit to that portion of this State through which it extends, and to a large extent of country beyond. It not only increases the convenience and comfort of travelers but assists miners and prospectors in getting in and out of their field of operations. It is the intention of the company to extend the road through Mono and Inyo counties, and by so doing they will increase the business facilities of both those counties and at the same time increase in a large measure the business done at this end of the line.

SEEK

health and avoid sickness. Instead of feeling tired and worn out, instead of aches and pains, wouldn't you rather feel fresh and strong?

You can continue feeling miserable and good for nothing, and no one but yourself can find fault, but if you are tired of that kind of life, you can change it if you choose.

How? By getting one bottle of BROWN'S IRON BITTERS, and taking it regularly according to directions.

Mansfield, Ohio, Nov. 26, 1881.

Gentlemen—I have suffered with pain in my side and back, and great soreness on my breast, with shooting pains all through my body, attended with great weakness, depression of spirits, and loss of appetite. I have taken several different medicines, and was treated by prominent physicians for my liver, kidneys, and spleen, but I got no relief. I thought I would try Brown's Iron Bitters; I have now taken one bottle and a half and am about well—pain in side and back all gone—soreness all out of my breast, and I have a good appetite, and am gaining in strength and flesh. It can justly be called the king of medicines.

JOHN K. ALLENDER.

BROWN'S IRON BITTERS is composed of Iron in soluble form; Cinchona the great tonic, together with other standard remedies, making a remarkable non-alcoholic tonic, which will cure Dyspepsia, Indigestion, Malaria, Weakness, and relieve all Lung and Kidney diseases.

Metallurgy and Ores.

WM. D. JOHNSTON,

Compressors.

MINERS' HORSE-WHIM.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The standard of the whim is bolted to bed-timber, thus avoiding all frame work. When required these whims are made in sections to pack on mules.

NATIONAL DUPLEX COMPRESSOR.

KNIGHT'S
Mining Water Wheel.
OVER 200 IN USE IN CAL.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. E. Haggin for Giant and Old Abe Co., Black Hills.

Wire Rope, Safety Cages and any Size and Forms of Cars. Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

MILL AND MINING MACHINERY.

F. A. HUNTINGTON,

No. 45 Fremont Street, San Francisco, Cal.

Oscillating Stamp Mill.

It has no Stems, Cam, or Tappets, and adjusts itself to the wear of the Shoes and Dies. For simplicity, economy, durability and effective working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power. Awarded First Premium and Medal at Mechanics' Fair, S. F., 1880.

Manufactured by
F. A. HUNTINGTON, FRASER & CHALMERS,
45 Fremont St., S. F., Cal. 145 Fulton St., Chicago, Ill.
Improved Patent Grinding and Amalgamating Pans, Concentrators and Gold Amalgamators; also, Steam Engines and Mining Machinery of all kinds. Send for circulars.

F. A. HUNTINGTON,
45 Fremont Street, San Francisco, Cal.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

Send for Circulars.

SHINGLE MACHINE.

For simplicity, durability and rapidity of action, these Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

SAWMILL MACHINERY,

Of all descriptions made to order.

F. A. HUNTINGTON,

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in Dewey & Co.'s SCIENTIFIC PRESS PATENT ABSTRACT, 252, Market St., S. F.

FOR WEEK ENDING JANUARY 9, 1883.

270,333.—REFRIGERATOR CAR—B. N. Bugbey, Sacramento, Cal.
270,411.—FISH TRAP—Jas. M. Frazer, Portland, Or.
270,564.—CABINET STEAM BATH—E. Sullivan, Cold Hill, Nev.
270,418.—ENGINE—P. K. Goodrich, San Francisco.
270,316.—MINER'S COMBINATION TOOL—John Jones, Oregon City, Or.
270,316.—MINER'S CANDLESTICK—John Jones, Oregon City, Or.
270,410.—CAR BRAKE—A. D. Kilborn and W. F. Smith, Tucson, A. T.
270,328.—VEHICLE BRAKE—F. I. Meyers, Healdsburg, Cal.
270,474.—HAND-TURNING TOOL—J. A. Plummer, Jr., & T. Sainford, Newark, Cal.
270,483.—ANCHOR—L. H. Rhoads, Bay Center, W. T.
270,529.—CANNING APPARATUS—Richard Wheeler, Alameda, Cal.
270,532.—SAWING MACHINE—D. W. Williams, Springfield, Cal.
270,356.—WRENCH AND PINNERS—Sam. L. Willmer, Anderson, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

ENGINE.—Periy F. Goodrich, S. F., Cal., assignor of one-fourth to Dexter Salisbury, of same place. No. 270,418. Dated Jan. 9, 1883. This invention relates to certain improvements in engines, and it consists in a means for expanding the steam or vapor which is introduced into the cylinder at a low pressure to a higher temperature and pressure by the admission of a quantity of explosive material into the cylinder with the steam at the beginning of each stroke, and igniting and exploding the same after the piston has commenced its stroke. The important feature of this invention is the starting of a piston upon each stroke in its cylinder by a low initial pressure of steam or other vapor, and then largely increasing that pressure without an undue shock or strain from the explosion. It is also for the purpose of intensely heating and expanding a volume of wet steam introduced into a cylinder at a low pressure, so as to obtain its greatest elastic power after its connection with the boiler has been severed, and finally it may be employed to superheat steam of a low temperature and pressure for any purpose after it has been cut off from the boiler.

VEHICLE BRAKE.—Francis I. Meyers, Healdsburg, Cal. No. 270,328. Dated Jan. 9, 1883. The invention relates to the class of vehicle brakes and to the means whereby power is transmitted from the lever to the brake locks. It consists in certain levers and shafts, and in the position of the latter. More particularly, it consists of two rocking shafts, to one of which, through a long arm and a connecting rod, the power is applied, and to the other, which carries the brake blocks, the power is transmitted by means of arms and rods connecting it with the first shaft. The second shaft is journaled higher up than the first, whereby longer arms may be provided and an increased leverage obtained, and the first shaft, by being low down, may have a longer arm connecting it with the main lever. The object of the invention is to provide a means, whereby the brakes may be applied with great power, and which will require but small force to operate them.

A NEW COURT.—The accumulation of business in the Supreme Court of the United States, resulting from appeals in excess of the number of cases which can be tried, has long called for a remedy. Not only is it proper that the Supreme Court should be relieved of much of the business which is now accumulating on its docket, but those having important interests at stake, which are dependent upon an authoritative decision, are entitled to some provision which will avoid the distressing delays that are now experienced, averaging about three years in each case. Congress has just established an Appellate Court to relieve the Supreme Court. Among those named for Judges of the Second district is Mr. James A. Whitney, L. L. D., who is receiving a very solid and influential support from the manufacturing interests. Mr. Whitney is one of the most scholarly men now practicing before the courts, and his long and successful experience in connection with patent litigation gives him peculiar qualifications. Mr. Whitney was at one time editor of the *American Artisan*. He is in every way suited to the position of Judge of the new court, and we hope the position will be tendered to him.

A MEDICINE of real merit, prescribed by many leading physicians, and universally recommended by those who have used it, as a true tonic, is Brown's Iron Bitters.

THE JUDSON MANUFACTURING COMPANY have removed their office and salesroom from 402 Front street to 329 Market. At their new quarters they will have goods of their own manufacture, such as tacks, brads, shoe and finishing nails, hardware, California Victor mowing machines, etc.

THE Mount Cory mine has been connected by telephone with the railroad station at Hawthorne. The distance is 11 miles.

Mining and Other Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

NOTICE OF DISSOLUTION.

OFFICE OF THE

South Comstock Gold and Silver Mining Company, No. 308 California Street, San Francisco, California, January 13, 1883.

Notice is hereby given that, pursuant to the provisions of Title Six of the Code of Civil Procedure of the State of California, a meeting of the STOCKHOLDERS of the SOUTH COMSTOCK GOLD AND SILVER MINING COMPANY, a corporation organized and existing under the laws of the State of California, will be held on MONDAY the 11th (5th) day of FEBRUARY, A. D. 1883, at the hour of TWO o'clock P. M., at said Company's office in room No. 4 of premises No. 309 California Street, in the City and County of San Francisco and State of California, to consider and vote upon the question of the voluntary dissolution of said Corporation and such other business as may properly come before said meeting.

By order of the President and Board of Trustees,
J. M. BUFFINGTON,
Secretary.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS. All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

- NO. 1.—The most Powerful Explosive Compound now in use here.
- NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
- NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much finer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same.

BANDMANN, NIELSEN & CO., General Agents, 210 Front St., S. F.

Contains no Nitro Glycerine or Chlorate of Potash, and is the only High Explosive Manufactured in America that does not contain these Dangerous Ingredients.

Price of Tonite Materially Reduced for 1883.

TONITE POWDER CO.,

No. 310 California Street, SAN FRANCISCO.

To Subscribers.

Notify us by postal card should it happen that you receive this paper beyond the time desired. We do not want any one to take it unwillingly. Don't receive it, nor fail to notify us, however, if you do not expect to pay for it.

LAND

Good land that will raise a crop every year. Over 12,000 acres for sale in lots to suit. Climate healthy. No drouths, bad floods, nor malaria. Wood and water convenient. U. S. Title, perfect. NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

—OR—

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrators are clear from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

Locke's Improved Lead Smelting Furnace.

The exhibit at the Denver Exposition of an improved lead smelting furnace, manufactured by the Lane & Bodley Co. of Cincinnati, Ohio, from designs furnished by Col. Jos. M. Locke, C. E., M. E., of Salt Lake City, Utah, attracted considerable attention, especially from those interested in the reduction of ores. In designing the furnace Col. Locke has combined all the later improvements and been guided in the selection and arrangement of the same by the advice of the principal smelters in the West. The main features of this smelter can be briefly stated as follows: The crucible binders are made of ribbed wrought iron in lieu of cast, thus securing lightness without sacrifice of strength, and at the same time greatly reducing the liability to breakage. This substitution of wrought for cast iron extends throughout the whole structure. The furnace being of the rectangular pattern, the ground plan of the base is that of a rectangle 9x7½ ft., with the corners cut off, thus allowing the uprights which support the deck plate to have foundations outside of the crucible binders. These uprights are rolled I beams, the grooves in their sides forming excellent racks for tools. The deck plate is also made of rolled beams placed some distance apart, the space between them being utilized as a conduit for any vapors escaping from the furnace. Pipes lead from the above conduits to the top of the building. The water jacket, which is in sections, is made of steel, in the following manner: The sheet forming the fire side of the jacket is shaped into a box over six inches deep without cutting the corners, so as not to have any riveted or welded joint exposed to the fire. The back plate is formed into a shallow box fitting into the other, the concave sides of both boxes facing outward, the outer edges of the two parts being flush, and in which position they are riveted and caulked, thus caving the joint entirely on the outside. Attached to the outside of the jackets are hoppers open at the top, and through which the cold water is supplied to keep the jackets cool, and from which there is an overflow for the hot water. This form, known as the open-topped jacket, claims advantages over the old method of closed jackets with an inlet and outlet pipe, in which case, if the openings of the inlet pipes are neglected or either pipe becomes obstructed, the results are serious, as steam would in such a case accumulate in the jackets to force out the water, and thus expose the jacket to being burnt.

In the present form such neglect or accidents become known at once to the furnace man, and in case of obstruction to the supply pipes the open-topped hopper affords an opportunity to furnish the jacket with water during the repair of piping. The end jackets do not come down to the crucible by about seven inches. The space so left is filled up with a small closed top jacket which can be readily removed. This construction does away with the old-fashioned brick breast, and in case of necessity enables the furnace man to rapidly open and close up the furnace at any time it becomes desirable so to do. All the piping for air, supply and discharge of water, and the valves to the same are so arranged as to admit of any jacket being removed without disturbing the connection of the remainder, and all valves are within ready reach of the furnace man. The ultimate economy of

these steel jackets has been fully demonstrated by experience at the large smelting works of the Horn Silver Mining Company, near Salt Lake, where five furnaces are in operation, each measuring 40 inches by nine feet at the tuyers. These five furnaces during the first

Our New Dress.

The MINING AND SCIENTIFIC PRESS will appear to its subscribers this week like an old friend refreshed, cleansed and redressed after a long journey. Our old reading type bore well

to draw closer to us in the support of our enterprise. The expenditure for our new outfit is a sign of our devotion to the work, and we hope it will lead to reciprocal effort on the part of our patrons in the way of prompt renewals and kind words which will enlist others to give us their support. There are thousands more who should read the PRESS, and probably would if they should hear, from those who know it, of its value.

To our editorial friends, who are typographical experts, we can but appeal for kindly judgment. They know well that it is hard to get a new suit with all the seams properly pressed at the first appearance. Enjoy what is good and overlook defects. It is a good rule in all affairs.

American Institute of Mining Engineers.

The papers read at the more recent meetings of the American Institute of Mining Engineers have been of a character of much greater interest to miners on this coast than formerly. Until within the past two years nearly all the papers were on subjects more directly connected with the coal and iron interests of the country. The precious metal interests were seldom considered. The reason was, of course, that the more active members of the Institute, and those who wrote most, were professionally engaged among the coal and iron mines.

Now a change has taken place, and many of the gentlemen who are members of the association come out to this coast among the gold, silver, copper and lead mines. We see the result in papers which treat of matters connected with precious metal mining subjects which interest other miners than those who work in coal and iron.

It seems to us that this broadens the field of usefulness of the association very greatly indeed. Not only are there more papers read, but the proceedings, as published, are of greater value to a more general class. It cannot be said that the mining engineers of the coast who reported on or managed the great gold and silver mines were ever a very communicative class. Whatever they knew they kept pretty much to themselves. Messrs. Hague, Bowie and Goodyear published, as did Messrs. Kustel, Aaron and Phillips, but outside of these few but little from the pens of this class of the community ever came into public print.

The public have been dependent almost entirely on such journals as the MINING AND SCIENTIFIC PRESS for such details of mining and metallurgy as could be procured. The engineers were exceedingly reticent, and little more than generalities could be gleaned from them. The three or four attempts to form a society of mining engineers on this coast met with failure.

Now, however, that the American Institute of Mining Engineers has within it so many of the profession both competent and willing to go into the science of mining and metallurgy of the precious metals, and lead and copper as well as iron and coal, there is hope for us on this coast.

This makes the American Institute more of a national and less of a local institution. The papers will be welcomed everywhere instead of in one section only. The miners and metallurgists of the country will look to members of the Institute to elucidate knotty problems, and to give them the science essential to their business. We see in this a better field of usefulness for the Institute and an opportunity for it to develop into a much larger society than it ever has been.

THE LOCKE PATENT LEAD SMELTING FURNACE

six months of 1882 had an output of over \$2,000,000 in value.

The shape of the furnace internally is as follows: From the tuyers upwards the water jacket has a bosh on the sides, thus increasing the width to five and a half feet; the ends are perpendicular from the top of the jacket; the sides are perpendicular to the feed door, making the shaft five feet by five and one-half feet. The height should be adapted to the character of the ore to be worked. The Lane & Bodley Co. have a Western office at Salt Lake City, Utah, of which Col. Locke is manager.

the heavy task laid upon it, but its work is done.

This week we have the new type, with its sharp outlines and clear impressions, which we trust may make our paper all the more welcome, especially if we can, as we hope to do, make our selections of facts more pertinent and our deductions therefrom more vigorous and valuable than heretofore. The new type will also prove an acceptable comparison to the finer engravings which we expect to introduce in greater abundance than before.

The improved appearance of the paper may prove, we trust, an incentive to all our friends

CORRESPONDENCE.

The Black Sand Question.

Reason of Loss of Gold.

EDITORS PRESS:—Knowing the willingness of Professor Hanks to lend his time and ear for the investigation of any interesting fact connected with the production of more gold, I made the request for a day of his time, that together we might closely examine into the "black sand" question, as connected with hydraulic mining. I had just returned from the gravel mines of the Red Hill Hydraulic Mining and Water Co., located near Magalia, Butte Co., Cal. During my stay there a partial clean-up was had, in which I participated with the view of studying the character of gold and the best mode for saving the highest percentage. During the clean-up I observed that magnetic iron and iron in its various forms, from the size of beans to the finest pulverized "black sand," was moving down the sluices in large quantities. A cursory examination disclosed the fact that very minute particles of mercury were attached to the iron. I saw at once that here was a matter for investigation, as a minute particle of gold must be behind this mercury for it to thus attach itself to the iron. Black sand in all our hydraulic and drift mines is abundant, and that it contains more or less gold is universally known; but this gold has generally been considered free, and in a condition to be saved by careful washing. Although I had read of others' ideas and experiments on the black sand question, yet, like too many other hydraulic miners, have given the subject heretofore but little attention as connected with this class of mining. I now concluded on a very thorough investigation, and for this purpose collected a quantity of the iron, varying in size from coffee grains to the finest, and to the examination of this requested the Professor's attention and assistance. A general examination was first made through the Professor's powerful microscope, and the first view revealed a secret of much value to me, and should be to all hydraulic miners. Here was black sand and iron ore being washed off by the hundreds of pounds daily, much of which carried gold coated with a film of iron so thin as to prevent the adherence of mercury, and yet discernible as gold through the microscope, but not to the naked eye; some where mercury would attach itself to abraded points; other specimens so black as only to be suspected, but which the blow pipe revealed to be gold; "rusty gold" completely enveloped, and having no affinity for mercury; and with all this some particles of very fine bright gold.

I must say I was surprised at seeing so much gold in such condition, none of which is secured by our present system of washing. The Professor assured me he had examined black sands from other hydraulic mines with similar results, and only wondered that hydraulic miners before this has not given the matter more attention. It did not take many glances through the microscope to satisfy me that I had business ahead, as the stoppage of such a loss must be arrested as soon as possible. We worked, calculated and speculated on the value of the gold associated with the black sands washed off in the working of our hydraulic and drift mines. And here let me say, as first expressed by the Professor, the saving of these sands, when once entered upon by the hydraulic and drift miners, will solve, in a great degree, the debris problem; for the reason it will pay the hydraulic miner to change his mode of dumping debris. On this proposition I think I can say the Red Hill Company will lead off. On this question, however, I may have more to say hereafter. The microscope having revealed so much, I now concluded to find the value per ton of the sands of various degrees of fineness. To this end the first operation was sizing the ore, which resulted as follows, 100 being the standard:

No. sieves.	100 standard.	Val. per 100	Val. per ton
Ref. 5 and 10 mesh	20.75	\$11.10	\$222.00
" 10 " 20 "	1.20	34.20	684.00
" 30 " 40 "	7.25	2.70	54.00
" 40 " 60 "	63.41	24.00	480.00
" 60 " 100 "	7.29	.60	12.00

This makes an average of \$290 per ton. As extravagant as these figures may seem, there is no getting away from the gold buttons in hand. It is proper to state that between the sizes of 5 to 20 mesh were several pieces of iron quite heavily coated with rusty gold, hence such large results; this may and yet may not be exceptional; further testing will determine. That which attracts my particular attention, and goes further to convince me of the value of these sands, is the result of that as sized between 40 and 60. I can see how this grade of "black sand" is likely to possess the value independent of the rusty gold by gathering and holding in its strong, magnetic, if you please, embrace, the finer free gold. The further I progressed in these experiments the more astonished I became, and yet the Professor had prepared my mind for satisfactory results. I could not at first believe there was one-quarter the value enveloped in these black sands. That these sands generally, from productive mines, properly concentrated, will pay \$100 per ton on the average, I have not the least doubt. So much for the experiment of considerable labor made for my satisfaction, but which I give to the public for the reason I engaged the time of Mr. Hanks,

who is working in the interest of the State, and in compliance with my promise to him to do so at the start. Whether these tests will awaken any interest in the minds of hydraulic, drift and placer miners, or not, concerns me but little. I can only say they should. I am now engaged in more extended experiments, and hope in time to solve two important problems: First, how to mechanically and cheaply extract the sands, and not interfere with extensive working. Second, how to practically and cheaply extract the gold. The latter, however, to me, is a more simple problem than the former.

ALMARIN B. PAUL.
San Francisco, Cal., January, 1883.

Notes From Eureka, Nevada.

[From our Regular Correspondent.]

There has been a great deal of comment in regard to the Albion affairs during the week. By many persons the amount of the company's indebtedness has been shrewdly guessed, while others have missed the mark by a great many thousand dollars. I have not been in the mine since my last report to the MINING AND SCIENTIFIC PRESS, but am assured by those who have that there is as much in sight as ever. The new sections of

The Accumulator at the Eureka Con.

Have been set in place. It is expected that the pipes and fittings will be attached and all ready to steam up on Thursday next.

At the Phoenix some of the tributers have been shipping ore, but have not yet got in their returns. It is said that the Jackson will shortly be started up by the company, but of the truth thereof I know naught. Mr. E. N. Robinson has bonded

The Eagle Series of Claims.

Lying southeast from the Jackson, that Joe Potts in his lifetime held to be a branch extension of the Ruby Hill mineral belt. Not sufficient work has been done, however, to determine whether his theory is correct or not. The claims in question are three in number, known as the Eagle, Blake and Connor, each 200 feet wide and 1,500 ft. in length on the lode. If bold iron croppings indicate favorably, it is a good property. Ten men are at work prospecting on the ground. At the bottom of an incline shaft on the Eagle I found iron, sand, clay, spar, and just enough of low-grade ore to swear by. This was at a depth of 27 ft. from the surface on the incline. There is a good double compartment shaft on the Bayard Taylor mine down 150 ft. that is situated within a stone's throw to the eastward of the incline shaft above mentioned, and on this a whim is to be set up. What the plan of operations is I did not learn, but there is some low-grade ore in the mine, and a big cave that has not yet been explored, as I learned from one of the owners three years ago, since when it has been lying idle, with exception of assessment work done on the ground. Indications point to the probability of the shaft being carried down to a greater depth, say to 300 ft., whence a crosscut driven out under the Eagle series would be a good thing to prospect both properties.

The Eureka Tunnel

Is looking about the same as it has been for several weeks past. Ore is being shipped at the rate of eight to ten tons per day that works about \$100 per ton. The output might be increased if the hoisting capacity were equal to removing the waste rock, which is not the case at present. It was intended to enlarge the main shaft and place the new engine on it, but a careful survey of the workings has shown the better plan to be the enlarging of a winze sunk 100 feet west of the main south drift. This is being done, and the timbers are framed ready to set. The advantages of sinking a working shaft and placing the engine at this point are various. The ground is more favorable for sinking, there is already a splendid prospect for ore in the winze, and the ore deposits at the south are dipping almost vertical, but with an inclination towards it. In addition to the advantages named there is a reasonable probability of finding a continuation of the first ore body discovered in the tunnel, which has made off in several directions, but in stringers too small to follow considering the means at hand to do the work. The south drift has been driven to the El Dorado Con. line on a seam showing fine indications for ore, but nothing has been discovered worth mentioning. Yet the ground looks so well that it seems a pity not to explore it thoroughly. It will be done in good time, says the worth foreman, Mr. Wm. Maxwell, than whom a better man could not be selected for the place. Ventilation from the surface is the strongly apparent necessity. It must be had, and how to get it with the best advantages and most profit to the company, is now a matter under consideration.

The Bald Eagle and Pioneer

Mines have been consolidated, the Pioneer people agreeing to furnish an equal amount of capital with the Eureka (Nevada) Silver Mining Company. An English corporation will conduct the business of the company in London; 60,000 new shares will be issued to raise capital for working purposes.

Four men are at work taking out quartz ore from the Republic mine on Prospect mountain. The mine looks favorable. On the Chloride and

Bromide locations, adjoining, assessment work finished last month left them in a very promising condition. Possibly the next assessment work done on these claims will develop some ore in quantities sufficient to warrant further exploration, when doubtless a capitalist will happen on the ground and offer a few hundred dollars for the property, which in any ordinary camp in Colorado he would be ashamed to offer for the same as many thousands. What a shame it is that this, the best mineral section in America, should receive so little attention from

The Moneyed Men of San Francisco.

I will guarantee to any man who will think it worth his while to take me up, that he shall receive \$50 for every time he sinks a hole in the ground to a depth of 10 ft. anywhere (in a limestone formation) within the boundaries of Eureka mining district, and fail to find rock that, upon being assayed, will not be shown to contain silver or gold. We have a magnificent field for legitimate and profitable mining operations, but are greatly in need of the capital required for development purposes. It must, however, come to us in time. The camp is in its infancy, and we have good inducements to offer. On Silverado mountain the Berryman Bros. are daily expecting to strike ore again—this time in a vertical winze, now down 45 ft. below the Diagonal tunnel level.

From the Silver Nugget nine tons of middle-class ore have been shipped to the Richmond furnace for reduction that assayed \$70 per ton in silver, and carried 40% of lead. It also contains silica in such quantities as to make it a very desirable ore for smelting purposes.

Yours truly, M. H. JOSEPH.

Wooden Water Pipe.

One of the best improvements for the good of the city of Ogden is that of the water works, inaugurated in 1881, and continued during 1882. A company, of which the city is part owner, operates the works. Water is taken from the Ogden river at an elevation of nearly 600 ft. above the city, and by means of pipes is conveyed to reservoirs on the bench back of the city. From the reservoirs pipes convey the water to various portions of the city and into residences. In the lower part of the city there is a pressure of 175 ft., ample for extinguishing fires by means of hose. The name of the incorporation is Ogden Water Company, E. H. Orth President and Joseph Stanford Secretary and Treasurer. The company have in use 12 miles of pipe in the mains, besides a large amount of service pipe, 34 city hydrants, 5 public drinking fountains, 2 public horse troughs, and over 200 subscribers using hydrants in residences and places of business. The pressure at the hydrants ranges from 75 to 100 lbs. A patent wooden pipe, wrapped spirally with iron bands, is used, so far giving good satisfaction. The works have cost about \$75,000, and the present revenue is about \$10,000 per annum. The expense of operating is merely nominal. Only a little attention to prevent any clogging at the fountain head and occasionally slight repairs are needed. Besides Ogden river as a source of supply, the company holds water rights in Strong's canyon. The above is taken from the Salt Lake Tribune, and we refer to it at this time to show the practical working of the improved wooden pipe patented by Houton some years since, and of which we gave an extended notice at that time.

SONORA NEWS.—Mr. G. H. Sharp, an old resident of Tombstone, returned from Sonora Saturday, having been absent some months. He left Hermosillo only a few days since, which place he reports improving. There are a good many Americans there, who add to the "push" of the place, if such a term is applicable to a country where everything is done manana (tomorrow). He says the Santa Maria property looks better than it did one year ago. They are doing a good deal of work, and have some ore. About one-half the machinery and lumber for their 60-stamp mill is on the ground, and the remainder in Hermosillo. The San Augustine (Shugart's) mine is turning out well, and he talks of enlarging his mill to keep pace with the production of ore. The ore continues rich. At the Las Delicias mine great developments have been made. They have opened the property in three places, all of which show an abundance of good ore. They have contracted for a 60-stamp mill and large hoisting works. Mr. E. E. Olcott, the superintendent, has returned from Boston, and is again at the helm. Crops along the Sonora river are up and looking well, and there is an air of greater prosperity than for a long time heretofore.—Tombstone Epitaph.

THE Bodie Miner's Union has elected the following officials for the ensuing term of six months: President, Watkin Morgan; Vice-President, Harry Keenan; Recording Secretary, John F. McDonald (re-elected); Financial Secretary, A. E. McMillan (re-elected); Treasurer, John Lawler (re-elected); Conductor, Humphrey Desmond (re-elected); Warden, John T. Read (re-elected); Finance Committee: Morris O'Connor, Roderick McDonald and John S. Long; Board of Trustees: M. Cullinan, S. P. Gallen (re-elected), John Prior (re-elected), Frank Bowden and D. E. Leahy.

MRS. MARY DOUGLAS has located a ledge known as the Buffalo claim, bounded south by the Empire mine, in Calaveras county.

Mining Laws.

Cutting Timber on Mining Claims.

The following letter to the Prescott (Arizona) Courier, from C. Y. Shelton, will be of interest to all miners:

It seems that in most large mining camps, and sometimes small ones, there are usually one or more persons who, in their judgment, know more law than others, and contend that if more than one lode exists in a mining location that outside parties have a right to go on, or enter, locate and hold one of the lodes; or, that they have the right to cut timber off it; or, that they have a right to build and reside on it; or, that they have a right to placer mine on it—all of which, if not intentionally, is calculated in its nature to create disturbance; or, that this or that man has not done his assessments; or, that he can't hold this, that or the other. Of course, all or most miners who want to know are acquainted with that particular section headed "Locators' Rights of Possession and Enjoyment," which gives them "the exclusive right of possession and enjoyment of all the surface included within the lines of their location, and of all veins, lodes and ledges throughout their entire depth, the top or apex of which lies inside of such surface lines, extended downward, vertically, although such veins, lodes or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side lines of such surface locations. But their right of possession to such outside parts of such veins or ledges shall be confined to such portions thereof as lie between vertical planes drawn downward, as above described, through the end lines of their location, so continued in their own direction that such planes will intersect such exterior parts of such veins or ledges. And nothing in this section shall authorize the locator or possessor of a vein or lode which extends in its downward course beyond the vertical lines of his claim to enter upon the surface of a claim owned or possessed by another."

And the following decisions are just received from Washington:

DEPARTMENT OF THE INTERIOR,
GENERAL LAND OFFICE,
WASHINGTON, D. C., Dec. 9, 1882.

C. Y. Shelton, Esq., Walker, A. T.—SIR:—I am in receipt of your letter without date, in which you state that all the mining claims in your vicinity are 1,500 ft. in length and 600 ft. in width, and a large number of them contain more than one vein; that it is rumored that information has been received from Washington that the original locators could only hold one vein or lode within the boundaries of their respective claims, and that outside parties could go upon such claims, locate and hold one of the veins. You ask if this is true, and whether outside parties have a right to enter upon claims properly located and cut timber therefrom, for building or other purposes, or reside thereon, or work the same for the placer mineral.

In reply I have to state, by the Act of July 9, 1865, the miner could only acquire and hold one lode or vein within the limits of his surface location; but the act of May 10, 1872, gave the locator of a lode claim additional rights; it granted to him a specific quantity of surface ground, the lode located and all other veins or lodes the apices of which lie within the surface lines of his location. Such veins are not subject to location or relocation so long as the original locator complies with the law; nor would a stranger be authorized to reside upon the claim, or cut timber standing thereon, without the consent of the owner; and any forcible attempt to do so would be a trespass. The owner's remedy would be in the local courts. See letter of Secretary of Interior to this office, under date of Sept. 30, 1882. (Washington Law Reporter, p. 636.) The locator of a lode claim acquires the right to all surface ground embraced within the exterior boundaries of his location, not previously reserved or appropriated, and the discovery of placer mineral thereon would not authorize an outside party to go upon the claim for the purpose of mining thereon. Very respectfully,

N. C. McFARLAND, Commissioner.

Now, some seem to think that the woods are free, and that they have a right to cut timber, reside, or placer mine where they please; defy law and man; take a part of that which belongs to others, or influence some one in that way, simply because they begrudge the law-abiding citizens their property. Such law violators are no acquisition to a mining community, and should look more to their reputation or apply for walking papers.

THE MINES OF CHIHUAHUA.—The Chihuahua Mail says: That an error exists in presuming that the silver, gold and copper mines which supplied the rich ores, the slag of which is all along the Chihuahuariver for miles, are far away from this city, we know to be true. It is estimated that there are two and a half to three million tons of this slag. We cannot, perhaps, see over twenty per cent. of it. Floods and dust have carried much of it away or hidden it from sight. We verily believe and have our reasons for believing that the oldest and best mines of all this Republic are within a radius of thirty miles of this State capital and many of the best within twelve miles of the city, and that hundreds of bonanza veins will be claimed and developed in the next six months on this ground.

BEFORE the end of January Vanderbilt starts for California with his sons and daughters and their wives and husbands. It will be purely a pleasure trip.

MECHANICAL PROGRESS.

Judging by the Fracture.

Whenever a line of shafting breaks, a boiler explodes or a rod or link snaps, an examination of the fractured surface of the iron is made. The inferences drawn from the examination are sometimes very unfair to the maker, at other times to the consumer, although the examiner himself would do no injustice to either. These unjust conclusions may frequently be ascribed to the prevalence of crude notions concerning the appearance which the fracture should present. Many suppose that if it is not fibrous, but crystalline, then the metal was unfit for use, and they charge the foreman or engineer with having subjected it to injurious and unnecessary strains which rendered it worthless at the time of the accident; or they enlarge the maker with having furnished metal of so poor a quality that it was unable to withstand extraordinary wear and tear. These charges are grave; they injuriously affect professional character, and they should be made with extreme caution, for the condition under which iron may assume and maintain a fibrous or a crystalline structure are yet matters of profound scientific inquiry. For a long time they have engaged the attention of the best engineers, who, recognizing the difficulties involved in the question, have been slow to form and to utter positive convictions.

The appearances of fractures being due to the positions assumed by the molecules of iron at the places. When the metal is fluid any change in their position may be accounted for. Thus, when pouring molten metal into a mold, that which cools rapidly will when broken exhibit a different fracture from the rest. It will be crystalline and lustrous, indicating hardness and brittleness; while parts of the same casting which cooled slowly will exhibit a dull granular fracture, and be found comparatively soft and tough. Here the fluidity of the mass readily permitted its molecules so to arrange themselves under the varied conditions of temperature as to impart to it the different qualities.

When the iron of which good shafting, boiler plate, rods or links are made leaves the fashioning it is of uniform quality. It remains solid while in use, and any molecular changes must be attended with difficulty, and be produced only by powerful external agencies. The opinion that the severe cold of our winters changes fibrous iron into crystalline, although generally entertained outside the profession, is received by engineers with many grains of allowance, and some of the best of them reject it altogether. Indeed, they have great reason to doubt whether iron, as it comes from the rolls or the hammer in the form of bar, plate or rod, has a fibrous structure. Take the rod to the draw bench, and draw it into wire in the usual way. You impart to it a fibrous structure; and so do all machines for testing tensile strain. The test pieces when drawn asunder exhibit fibrous structure, and this is assumed to show that they possessed such structure before they were subjected to the strain; but it proves nothing of the kind. As in wire-drawing the tendency of the operation is to cause the molecules to take the form of fiber; but had another method of rupture been employed the same pieces would have appeared crystalline, and by the popular standard been adjudged inferior. Nick them round, as is frequently done in the rolling mill, and, laying them flat between two supports, subject them to the force of a falling weight. They will break squarely off, and not a trace of fiber can be detected in the fracture. Had the same bars been tested in another familiar way, by making a nick on one side only, and then with a hammer bending them until they broke, the fracture would have been fibrous, the bending being so far a wire-drawing process as to arrange the molecules in fine lines. Whether the fracture be fibrous or not depends upon how the rupture came about, and to condemn iron because its fracture is crystalline, without taking into account the method of rupture, is most reprehensible. In thus pointing out the untrustworthiness of the fracture test we do not leave the questions involved without other and exact means of settlement. Poor iron is so because it is impure. One per cent. of carbon, silicon, sulphur or phosphorus seriously impairs the quality of iron, and the presence or absence of those elements can be ascertained with the greatest nicety by means of chemical analysis.—*Dr. A. S. Kennedy.*

Iron Rust as a Cement.

Most mechanics in iron have tested the cohesiveness of iron rust as a cement in the use of the ordinary joint packing made from iron filings or drillings, sal-ammoniac and sulphur, combined with water. The salt and sulphur are simply agents to rapidly and thoroughly oxidize the iron, which becomes, in its oxidized state, a cement. The effectiveness of iron rust as a cement is not confined to its action between iron surfaces; it is seen in the red sandstones, which consist simply of sand held in mass by iron rust, that gives it, also, its reddish hue, and in the common red bricks, which derive much of their cohesiveness, as well as their color, from the iron they contain. The process of the formation of red sandstone can be seen by the careful observer on some of our New England beaches, where this kind of rock prevails in the cliffs and the beach shingle. The slight winnows of sand thrown up by the increasing waves in some high tide may be found gradually hardening into stone under the combined action of sea, water

and air; and fragments may be picked up in all stages, from the crumbling sand, the cohesiveness of which will not bear its own unsupported weight, to the hardened shingle, which is essentially rock. And yet this sandstone, when quarried many miles from the sea, from beds that must have been deposited many centuries ago, retains so much water that it must be seasoned like wood before it is ready for building use. And this water is probably salt, for its effect on iron brought in contact with it is essentially the same as that of salt water on iron under any other circumstances.

A notable instance came under the writer's observation several years ago. A balustrade of iron bars, or balusters, seated in red sandstone, was taken down, and that portion of the iron that was removed from the stone was either a fibrous powder or a few strings of iron. In this instance the gradual disintegration of the iron by rust had been going on for more than 40 years, but it had been going on. The imbedding of the iron into the solid stone, protecting it from the weather, could not protect it from the moisture, probably salt moisture—in the stone. All of this disintegration could not be attributable to the absorption of moisture by the stone, as a portion of this balustrade was entirely within an inclosed building. If sulphur imparts activity to the process of oxidation of iron, when used as a component of the ordinary "rust cement," it is evident it is wholly unfit as a filling to seat iron into stone, especially into red sandstone. Lead is, perhaps, as safe as any material, as, while it will not be attacked by moisture to any appreciable extent, it will defend the iron from destruction.

In witnessing the operation of removing a heavy iron fence recently, which it was desirable to preserve for re-erection, it was noticed that, while the palings could be easily removed from their leaded seats in the stone base, it was necessary to start them from their connection with the horizontal bars, or rails, by sharp and repeated blows of a hammer. The cross section of the palings was a right-angled cross, or an X, and their bearing against the corresponding holes in the rails was, as carried around the outside, about four inches, by three-quarters of an inch in depth, or thickness of rail, making an area of bearing between the two surfaces of about three inches. Yet this comparatively slight area, as compared with the much larger area in the stone, offered a much greater resistance, showing the cohesive force of simple oxide of iron.—*Cotton, Wool and Iron.*

Shop Practice.

I well remember my first visit to a machine shop, and how I was impressed with the slowness of the work in process—the slow revolving of the shaft or pulley in the lathe, with no perceptible forward movement of the tool; the slow dragging of the planer bed, with a faint show of hurry on the back motion. This, doubtless, is a common impression, made on all who see such work for the first time. Having watched the lathe and the planer so long, it would seem that this apparent slowness would be less noticeable, but still I see it. Once in a while the brisk movement of five or six feet a second attracts attention, and I instinctively look to see if the tool stands the speed, and drop a word in recognition of the get-up of the man in charge. The other extreme of speed is more frequently met, and sometimes it is necessary to use a magnifying glass to see if things are really moving.

It is often annoying to notice this disregard of time on the part of the workmen, and yet I feel a degree of sympathy that prompts a word of apology. There is no doubt but that this everlasting slowness has become a part of the machinist's education.

He has come to fear nothing as much as the possibility of dulling a tool, seeming to feel much as one does when at work in the country, with the last sound chisel, and a mile or more from a grindstone. He actually seems to think that it is a part of his business to be slow.

Just to make the contrast striking, go into a brass shop and notice the way the lathe hand handles his calipers, scraper or burnisher, and see how he jerks the shifter from side to side; or, into one of our modern cooper shops, and see the man or boy put on truss-hoops, or paint barrels at the rate of two a minute. Then go back to the machine shop and see the sleepy lathe hand enjoying a good loafing job, with the slow feed and speed on that he dares to adopt. Or, another setting his calipers the fourteenth time to know if he dares to try the thing to see if it will fit.

There are some exceptions to this class of close workmen, and a few who look for the shortest way round, and really seem to try to see how much work their lathe or planer will do, in place of how little.

It would be well if master machinists would have an active eye to the active men, and encourage their efforts, at least by recognition if not by advanced pay, which would be the strongest incentive to an emulation of their example on the part of others.

I was once acquainted with a lathe hand who knew how to use hand tools. He was naturally kept at the ornamental turning of irregular shapes, and could turn out three times as much of it as anyone I ever knew, notwithstanding he spent much of his time at a grindstone; in fact, he had one of these useful articles placed very near his lathe.

I hope none of my brother "chips" will take offense at anything I have said. I would have him know his is not the only slow trade in the world.—*Cor. of American Machinist.*

SCIENTIFIC PROGRESS.

Practical Application of the Lenkoscope.

In a recent issue of *Engineering*, London, we find an account of a number of experiments by Dr. Koenig on the quality of different kinds of light by means of the lenkoscope, an instrument of his invention. It consists of a rhomboid of calc spar, a quartz plate and a Nicol's prism. When a ray of light enters the spar it is split into two rays, polarized at right angles. These traverse the quartz and Nicol. When analyzed they show two spectra of absorption bands, and the peculiarity is that, where the bands occur in one, the other spectrum is of pristine brightness, so that the two spectra overlaid give a continuous spectrum. The number of bands is increased by increasing the thickness of quartz, and they can be shifted by rotating the Nicol. It is possible, therefore, by rotating the Nicol to make the colors in each spectrum produce white light together. When different kinds of light are examined by the instrument, different amounts of rotation of the Nicol are required to bring the two spectra into conformity, and the angles of rotation are a gauge of the color-quality of the light examined. According to the results communicated to the Physical Society of Berlin, Dr. Koenig finds that the angle for steampar candles is 71.20°; for gaslight, 71.5°; for electric arc light, 79°; for magnesium light, 86°, and for sunlight, 90.5°. For burning phosphorus and the Drummond limelight the angles were between gas and the electric light. It thus appears that the magnesium light more closely resembles sunlight than that of the electric arc, a result confirmed by the fact that the aniline dyes, hardly distinguishable by gaslight, can all be distinguished by the arc light, except a few "bronzes," and even these are clearly distinguishable by magnesium, as by sunlight. Dr. Koenig has also tested Swan and Edison incandescence lamps, and finds that the luminosity increases at first in a much greater rate than the current increases. Doubling the strength of current very largely increases the luminosity. The highest angle reached was 78°, or very nearly that for the arc lamp. These researches of Dr. Koenig are of considerable interest, more especially as so little has been done in this direction.

BISULPHIDE OF CARBON LENSES.—PROPORTIONS OF LENSES.—We say in reply to a correspondent that we do not know of any telescopes with bisulphide of carbon correcting lenses having been made of late years. They were never a success. It requires the grinding and polishing of four surfaces for the correcting lens, and as there are no formulas, to our knowledge, for the bisulphide, you will have to make an experimental trial. For your front glass you may make the curves one to six or nearly a plano-convex flat side next the eye, the radius of shortest curve about six times the diameter of the lens. For the correcting lens the diameter should not be less than one-third the diameter of the front lens. Its general form should be plano-concave; and as the dispersive power of bisulphide is more than three times as great as crown glass, its refractive power being about 50% greater, you may make the side next the object glass plane, and the side next the eye convex on the inner side and plane next to the eye, if convenient to do so. This will require only one curve to be altered for final correction. To start, make this curve the radius of the first surface of the front lens, and place the lens about one-third the focal length of the object glass from the eye.

GUM ARABIC IN CERTAIN CHEMICAL REACTIONS.—Jules Lefort and P. Thibault find that in dilute solutions gum linders the precipitation of metallic sulphides. In concentrated solutions, or when the proportion of gum is small, there is a precipitation more or less incomplete. The precipitation of the metallic oxides is also prevented whilst in the presence of gum, quinine, cinchonine, morphine, strychnine, brucine and veratrine are not precipitated by the usual reagents, ammonium phospho molybdate, potassiummercuric iodide and tannin. The gum does not dissolve the various precipitates formed or prevent their formation, but merely holds them in suspension. These results have a certain physiological importance. Most inorganic fluids contain glutinous bodies, and it is hence possible to understand the simultaneous presence in a soluble state in the animal and vegetable cellules of compounds capable of acting chemically upon each other. In analytical operations gum and analogous bodies must be removed before certain determinations can be effected.

POTELINE.—M. Potel recently submitted to the French Society of Encouragement a new substance, named after himself, "Poteline," and which appears to be susceptible of numerous applications. It is said to be a mixture of gelatine, glycerine and tannin, and is, according to the inventor, absolutely impermeable to the air. When warmed it becomes liquid, or nearly so, and may readily be worked into different shapes. M. Potel is reported to have made corks of it which form an economical substitute for metallic capsules, securing a hermetic closing, and to have used it as a coating to preserve meat. At a temperature of 112° it becomes almost liquid, and when applied to meat will, it is claimed, kill the germs of putrefaction and prevent the entrance of new germs. According to the inventor, meat thus treated will retain all its freshness for a considerable length of time.

Cheapened Aluminum.

The improved process of producing the metal aluminum, recently reported from England, does not cheapen the product anywhere near enough to bring the metal into serious competition with iron. The inventor, Mr. James Webster, of Hollywood, near Birmingham, Eng., claims, however, to have found a way to solder and weld the metal. If this claim is true, and the methods are practicable, the improvement is likely to greatly extend the usefulness of the "coming" metal.

Mr. Webster's process of reducing the metal is described as follows:

A given quantity of alum and pitch, which are first finely ground, are mixed together and placed in a calcining furnace, by which means 38 per cent. of water is driven out, leaving the sulphur, potash and alumina with oxide of iron. The calcined mixture is then put into vertical retorts, and steam and air are forced through, which leaves a residue of potash and alumina only. This residue is afterwards placed in a vat filled with warm water, which is heated with steam. The potash is thus leached out, and the alumina left as a deposit. The potash liquor is then run off, boiled down, while the alumina precipitate is collected in sacks and dried. It is then ready for making chloride of aluminum. The alumina deposit thus obtained contains about 84 per cent. of pure alumina, while that which is obtained by the old process of precipitation has only 65 per cent. Mr. Jones, the Wolverhampton borough analyst, certifies that the constituents of Mr. Webster's alumina deposit are as follows: Alumina, 84.10; sulphate of zinc, 2.08; silica, 7.40; water, 4.20; alkaline salts, 1.62. In order to complete the process and convert it into aluminum, the chloride of aluminum is treated with sodium, in order to withdraw the metal. Aluminum is afterward alloyed with copper, silver, and other metals. It is used for the manufacture of bismuth bronze, aluminum bronze, or any other alloys.

A CURIOUS PHENOMENON.—The Virginia *Enterprise* gives the following particulars in regard to a tunnel that resents being a tunnel, and insists upon being just the opposite. Its location is Castle district, at a point about five miles north of Virginia City. It was run about four years ago into the side of a steep hill, and was originally about 40 ft. in length. When in about 15 ft., the tunnel cut into a soft, swelling clay, very difficult to manage. After timbering and striving against the queer, spongy material till it had been penetrated some 25 ft., the miners gave up the fight, as they found that it was a losing game. Being left to its own devices, the tunnel proceeded to repair damages. It is very plainly shown that it resented the whole business, as its first move was to push out all the timbers and dump them down the hill. It did not stop at that, but projected from the mouth of the tunnel a pile of stopper of clay the full size of the excavation. This came out horizontally some eight feet as though to look about and see what had become of the miners, when it broke off and rolled down the slope. In this way it has been going on until there are some hundreds of tons of the clay at the foot of the hill. At first it required only about a week for a plug to come out and break off, then a month, and so on till now the masses are ejected but three or four times per year, yet the motion continues, and to-day the tunnel has the better of the fight about four feet.

SOAP MANUFACTURE.—H. Heckel has obtained a German patent for the manufacture of soap without loss of glycerine. The practice at present is to saponify the fats with alkalies without any previous treatment of the grease, for the purpose of decomposing it. The result is a slow saponification, and all the glycerine that does not remain mechanically suspended in the soap is carried away in the alkaline solution and lost. The design of Heckel is to prepare the fats for instantaneous saponification and economize all the glycerine. The glycerine is first extracted from the fat in its neutral condition, by the direct action of steam and water under a pressure of 75 kilos. The whole process of soap making is abridged by the system, and it is claimed that the soap itself is superior. A digester with diaphragm and rotary pump form the special apparatus.

A LATE NUMBER OF THE Idaho Statesman says: "The activity of volcanic action in the Snake river lava beds, near the line of the Oregon Short Line railroad, is driving many of the graders from the work. In an area of about 22 square miles, at short distances apart, smoke and flames of a peculiar odor, color and shape issue from the chasms and seams in the lava. The irritating sulphurous vapors in themselves cause many to quit work, while the unusual agitation of the boiling springs and the general commotion all over the fields of lava has caused a superstitious fear to take hold of many of the railroad hands, and they are leaving the section terror-stricken. The whole area has the appearance from a distance of being on fire."

A NEW KIND OF ALUM, under the name of double alum, has been introduced in the German trade. It is a transparent sulphate of alumina, but has a larger proportion of the latter than usual, and is free from iron and acids. For many industrial purposes, such as the preparation of paper, etc., it will, it is claimed, present some advantages.

MINING SUMMARY.

Mining Share Market.

The Tehichepa Disaster.

Before daylight on the morning of Saturday, Jan. 20th, a train of cars left standing without a locomotive near the summit of the Tehichepa pass, on the S. P. R. R., rushed down the grades and around the sharp curves until a part of the train jumped the track and was instantly wrecked; almost immediately the cars took fire and were consumed. Many were killed by the shock, and others perished in the flames, unable to extricate themselves from the wreck. It was the most appalling railway disaster ever occurring on the Pacific coast. The following is the list of the killed and wounded :

L. Wethered, dead; Major Larrabee, dead; Capt. A. L. Waterhouse, wife and two children, wounded; Miss Ida Brown, wounded; Mrs. J. K. Brown, wounded; Lawrence, the porter, dead; B. A. Schlegel, dead; Mrs. Cassell, dead; H. A. Oliver, dead; Miss M. E. Squires, dead; Mrs. Hatch, wounded; Gov. Downey, wounded; Mrs. Downey, dead; Wright, the porter, dead; Thomas Keegan and F. Grompf, both dead; C. K. Pierson, express messenger, dead. [Mr. Pierson was the son of the Utah correspondent of the MINING AND SCIENTIFIC PRESS. —EDS. PRESS].

This makes only 12 known to be dead, but several others who boarded the train at the way stations are believed to have perished.

Much mail matter was burned, including the edition of the RURAL PRESS mailed to subscribers in the southern counties. Unfortunately, we are unable to replace these papers.

THE OSTRICHES AT WOODWARD'S GARDENS are attracting much attention, and they are

well worth a visit. There are several varieties of the ostrich, and the specimens on exhibition afford a rare opportunity for studying the characteristics of this wonderful bird—the largest of all the feathered kind now in existence. Two varieties—the Emu and the Cassowary—have been on exhibition at Woodward's for some time. These birds, however, are much smaller than those which recently arrived here from South Africa via New York. The latter are the true ostrich, being much larger and differing much in other respects from the smaller varieties. The males of the variety recently arrived sometimes reach 300 pounds in weight, and stand eight feet in height. There are 22 of these noble birds now at Woodward's, which have been brought here to be domesticated for their feathers and eggs. Some varieties of the ostrich when young are very palatable as food. The present is a rare opportunity for seeing them which will not be continued long, as the birds will soon be removed to the "ostrich farm," which is being prepared for them in the interior of the State. The last China steamer brought to Woodward's another very interesting bird novelty—known as the Mandarin duck. This bird is quite rare and specially noted for its beautiful plumage. It is well worth a visit to the Gardens to see it.

A FULL feeling after meats, dyspepsia, heart-burn and general ill health relieved by Brown's Iron Bitters.

California.

AMADOR.—Amador *Ledger*, Jan. 20: The Oneida company has put a number of men to work in preparing the ground in the neighborhood of the mine for sluicing. It is said that there is some first-class gravel which has never been worked, some of it prospecting as high as 15 to 20 cents per pan. The intention is to run it through sluice boxes, employing three gangs, 4 men to each gang, in shoveling it in. The operations are carried on under the direction of A. Yelmini.

OCURE.—This claim is owned by the Page brothers, and is located one and a half miles west of Plymouth. We are informed that in the last two weeks the nice little sum of \$1,500 was taken out by pounding in a hand mortar the richest of the ore. It bids fair to become a famous mine.

MISCELLANEOUS.—The Cleveland placer claim at Volcano has been running steadily for three months past, employing 5 men. The work mainly consists in taking out pay dirt, and getting it on the dump preparatory to washing, when the water supply enables them to do so. There are 4 owners in the claim. The gravel prospects handsomely; as high as \$2 has been taken from a single pan.

KELLY.—This quartz mine, three and a half miles above Volcano, is working constantly, with the small mill belonging thereto. This and the Downer mill, we believe, are the only quartz mills in operation in Volcano district at the present time.

VOLCANO.—Amador *Dispatch*, Jan. 20: The weather has been so cold and frosty that all the creeks are dried up, so that it is impossible for grave miners to work their claims. All the quartz mines around are still at work. The Acme mine is working steady. The Downs mine is getting out very rich rock. The mill is running day and night to its utmost capacity. The mines in Pioneer district are all getting out rock.

COPPER.—The Campo Seco Copper Company has concluded a shipment of 500 tons of copper, and now has under construction extensive smelting works. Fifty tons of castings are now on the ground for that purpose. There are at present 30 men employed, but the number will be doubled as soon as the present works are completed. The body of ore is 25 ft. in thickness, and contains about 15 per cent. of copper.

BUTTE.
THE PERKSHACKER.—Butte *Record*, Jan. 20: We received a call last evening from Mr. John Barrett, a long-time resident of Magalia, and one of the owners of the celebrated Perckshacker mine near the

ers in the celebrated Pershnucker mine near that place. He still adheres to his opinion expressed long ago, that it is one of the best mines in the State. Just now they are not drifting in the mine, for the reason that the cold weather formed ice in their ditches, which prevented them with power to run their pumps, and, while waiting that of Arctic and other obstructions to the free passage of the water, the pumps were allowed to lie idle, and the mine was flooded. They expect to have it pumped out in a short time and go ahead again with their daily work of taking out numerous specimens of coarse gold, besides ounces of fine dust.

CALAVERAS.
WEST POINT.—Cor. *Calaveras Chronicle*, Jan. 20
The Champion mine is being worked; prospects are
favorable. Wm. Henderson and Wm. Jones have
the management of the brakes. From what we can
learn good ore is being taken from the Carlton mine.
New machinery has been put on the mine, and work
is prosecuted night and day. Mr. Baker and Mr.
Richards run the engine. The Henry mine is shut
down at present. It is one of the leading mines in
this vicinity. The Star of the West, Tom Payne
Pride of Bummerville, Water Lilly, Gouldston and
several other mines are not being worked at present.

THE LEAVITT MINE.—We were shown some very rich specimens of quartz one day this week which were taken from the Leavitt mine, situated near the Big Bar bridge on the Moquelumne river. The rock was taken from a depth of 40 ft. and the vein at this point is large and well defined. Considerable work has been done upon the mine in the way of prospecting.

EL DORADO.
UNFAVORABLE.—Georgetown Gazette, Jan. 20

This winter so far has been very unfavorable to our mining interests. The sluice claims have nearly all been idle. Owing to the freezing weather of the past few weeks the California W. & M. Co.'s ditches have been very short in their water supply. Our mills have been shut down on this account. About the only work in the mining line being done is tunneling, drifting and sinking. General stagnation now prevails. Very little money is circulating, and many of our people are closely pressed. Financially, this is the worst season ever experienced here.

GREENWOOD.—Owing to the protracted spell of dry, cold weather dullness prevails. Mining operations are almost entirely suspended for lack of water and until the wished-for rains come news items, like every other benefit, will be scarce.

CRESCENT MINE.—*Greenville Bulletin*, Jan. 20. The pumps were started up last Friday and are working very well, lowering the water in the shaft 1 ft. per day. At this rate it will be but a short time till the Ophir vein can be reached from the shaft when work can be done to much greater advantage than at present. It is the intention of Mr. Davis to continue the drain tunnel around and above the shaft. When this is done it will intercept and carry off a large amount of water that now finds its way into the mine, and to that extent will reduce expense. The ore continues to be as rich as before, and the body increases in size with further development. Eight stamps are now running, 4 more having been started up on last Friday. Still other batteries will be put to work as soon as new ground is opened up, till the whole milling capacity shall be fully employed.

GRANITE BASIN NOTES.—Cor. Plumas National, Jan. 20: Basin froze up for the winter, and 2 ft of snow. Nothing doing. The parties that attempted to buy in with Swan & Ament have so far failed to

meet their agreement, by way of putting in the promised sulphur works and paying the amount stipulated in the agreement. So I think the sale a dead letter. See & Jolly are busy getting out good rock in their upper mine. They undoubtedly have two splendid little ledges that keep their mill busy during the summer. The Minto mill lies idle. If it would turn water so they could throw out the pipes, they would start the mill up and run through some 60 or 80 tons already stoped out, but the circles are about 7 ft too long. There are a few placer mines in this section of the country, but at present the outlook for water is bad, and some of them will have to use the old rocker in the spring.

SAN BERNARDINO.

THE PROVIDENCE MINES.—San Bernardino Times, Jan. 20: The Bonanza King Con. Mining Co. smelt is the most complete one on the Pacific slope. The mill is 10 stamp—with power for 20—crushing capacity, 30 tons per day; stamps, 865 lbs.; 6 Boss' Cone pans 5 ft. 1 clean-up pan, 3 9-ft settlers and 10-ton Blake's improved rock breaker. The engine is a marvel of beauty and finish.

ILLINOIS SHIPMENTS. The pulleys for the pans were geared too high and the connecting water pipes from the springs to the mill got out of fix, and other little drawbacks, very little being done until January, since which time the Bonanza mill has been turning out bullion at the rate of 60,000 ozs a month, or \$2,000 a day.

STRIKES. Several new strikes have been made in the mine, notably one from No. 2 winze, running diagonally across the main ledge several feet wide. This find is liable to connect the Bonanza with the Kattler mine.

SAN DIEGO.

NEW MINING DISTRICT.—San Diego News, Jan. 20: At a miners' meeting called and held at the headquarters of the Menifee Mining Co., San Diego county, Cal., on Jan. 10, 1883, for the purpose of forming a new mining district, C. Herketh was called to the chair and L. M. Wilson appointed Secretary, when the following proceedings were had: John E. Stuart, M. Probst, Beebe J. Denning and J. H. Binet were appointed a committee to draft a set of by-laws to govern the district, and reported as follows: Sec. 1. "This district shall be known as the 'Menifee Mining District,' and is bounded as follows: Beginning at a point where the old sheep camp wash intersects and is crossed by the California Southern railroad, and about three-fourths of a mile northerly from what is known as Cottonwood canyon, and running easterly along said old sheep camp wash to the old sheep camp; thence due northeast to the main wagon road leading from Lamb's blacksmith shop to Pinnacle railroad station; thence easterly to Coyote springs; thence easterly to San Jacinto toll-gate; thence southerly to Ticknor's store; thence south-westerly to the Temecula railroad station; thence northerly along the line of the California Southern railroad to place of beginning."

SHASTA.

FROM WHISKYTOWN.—Cor. Shasta Courier, Jan. 20: Andrew & Kesler have a quantity of quartz ready to mill, but Johnnie says there is not enough water to drink, let alone run an arrastra. At Mad Ox there are 400 tons of quartz on the dump. Several days ago they made a short run of 18 tons, but had to shut down on account of scant water supply. The new mill works like a charm. It is a great credit to the late energetic superintendent, Mr. Farham, under whose supervision it was constructed. Zent & Butler are engaged in the development of their mine, and are keeping a sharp lookout for nuggets. Low & Beagle are opening up a ledge above the Mad Ox. Harrison & Jackson present the appearance of prosperous miners. Bell & Mahoney have leagued together to assault quartz upon Grizzly. J. Stroud has purchased the interest of Arnett & J. Williams on Dog Gulch.

SIERRA.

QUARTZ.—Mountain Messenger, Jan. 20: Stephen Spencer's quartz mill, situated below the Ruby mine, is all ready to run when water comes. His men are at work getting down quartz.

BIG.—The old Union claims at Gibsonville continue to pay as well as ever. An immense deposit of rich gravel has been tapped, and the extent of it is not yet known.

JEROME YORK has got his arrastra in Slug canyon running. The late cold snap has interfered with his work by shutting off the water. Mr. Schofield, of the North America mine, is running ahead in hard rock, but expects to complete his tunnel in about 7 weeks. He has prospected the ground by shaft, and is now running a tunnel to work the ground.

TRINITY.

DEADWOOD.—Trinity Journal, Jan. 20: Mr. Frick was in this week, and from him we learn that Frick & Davis have their lower tunnel in about 200 ft on the mine recently purchased from Gibson & McDonald Bros., and that they expect to strike the lode in 80 ft more. This will open the mine 80 ft lower than it has been worked and about 160 ft below the surface. In running this lower tunnel a small but very rich stringer was cut lately. Other mines in the Deadwood district are reported as not only "holding out," but constantly improving.

TUOLUMNE.

THE HESLER.—Tuolumne Independent, Jan. 20: This mine, a long while in the shadow as a good investment, has recently come to the front. The mine is owned by a French company, who have furnished a good many hopeful twenty dollar pieces. With these they also sunk a shaft 800 ft deep in barren rock—in consequence, the property has been discouragingly down at the heel. Recently the superintendent was induced to run to a known chute farther south. This chute of ore was discovered in early times, and, strange to say, was only prospected to the depth of 10 ft. At a depth of 400 ft, on a drift 10 ft wide, they have found no hanging wall—a part near which the vein is said to be the richest. The ore they are now taking out is supposed to mill from \$7 to \$15 per ton—and the cost of mining and milling is about \$3 per ton—leaving a splendid profit for the company. The chute will pay from the grass roots. The miners pan out from 12 to 15 cents from a drill hole 2½ ft deep. Stocks are again up at Quartz mountain.

Nevada.

WASHOE DISTRICT.

UNION CON.—Enterprise, Jan. 20: The joint Sierra Nevada east crosscut on the 2900 level is making good headway. Being now well out from the

station, blasting may be pushed. The rock is the regular Comstock vein porphyry, with streaks of porphyry and clay. All this quartz is metal-bearing. The joint Mexican east crosscut on the 2500 level is passing into ground showing more quartz than was at first seen, but it still has a considerable distance to go to reach the point where it is hoped that ore will be found. The metal-bearing seams of quartz appear to be stringers or feeders from some larger body of quartz.

OPHIR.—The broken spur-wheel was replaced and in operation last Sunday. All the machinery is now in excellent condition. At the joint Mexican winze all is progressing well. A working station is being cut out at the 3100 level. Two sets of timbers have already been placed in position, and in less than two weeks the whole station will be completed. The material encountered in cutting out for the station is the same as was found in the bottom of the winze.

CON. VIRGINIA.—The south drift on the 2700 level is being advanced at the usual speed. The face continues to show quartz giving low assays. All the hoisting of men and rock is now being done at the C. and C. shaft, pending the change of the pumps at the Union shaft. The sending of the men down at this point interferes but very little with the regular work, as no ore is now being hoisted.

CHOLLAR.—The main south drift has crossed the line into Potosi ground and has passed into vein material that gives low assays. The ground is comparatively dry, and is of such character that good headway can be made of it. The seams of metal-bearing quartz appear to be feeders from the main vein, which lies to the west, and when a crosscut shall be run in that direction something of value is liable to be found.

MEXICAN.—A working station is being cut out at the 3100 level. This will be completed in less than two weeks, when an east crosscut will be started. The material found in this large opening is as yet about the same as that passed through by the winze. The joint Union Con. east crosscut on the 2900 level is progressing at the rate of about 20 ft per week, and the material is steadily improving.

SAVAGE.—The joint Hale and Norcross drift on the 2600 level is being advanced at the rate of 40 ft per week. The drift has passed through the belt of soft material which required such close timbering and which was so wet as to somewhat retard operations. The rock is now of a good blasting character and will allow of better progress being made.

SIERRA NEVADA.—The east crosscut on the 2700 level is still following a crosscourse of quartz of good appearance. In a few days this crosscut will reach a point where a change of ground for the better may be looked for. On the 2900 the north drift and the east crosscut joint with the Union Con. are making good headway in favorable ground.

YELLOW JACKET.—Over 60 tons of very fair milling ore now daily being extracted. A considerable amount of prospecting work is in progress, and new deposits of ore are liable to be found almost any day, as occasional bunches of paying ore are encountered in several directions.

HALE AND NORCROSS.—The joint Savage drift on the 2600 level has passed into harder and dryer rock. This allows of better progress being made, as the close timbering is not required which was necessary while in the belt of soft, wet ground. The rock contains seams of quartz that give low assays.

TAYLOR DISTRICT.

MILL.—Eureka Sentinel, Jan. 20: The remains of the old Lemon mill have been bought by the proprietors of the Monitor mine, Taylor District, and will be removed to its destination as soon as the weather permits. These remains consist of three pans and one settler. After this last haul there will be little left of the old landmark but the frame.

TUSCARORA DISTRICT.

ELKO CON.—Times-Review, Jan. 20: During the past week the west crosscut from main drift of shaft No. 1 has been extended a distance of 10 ft. In the main drift good ore has been encountered with every indication of improvement as the drift is advanced.

INDEPENDENCE.—The west crosscut on the 300 level was advanced to ft the past week. The south drift, 400 level, has been extended 17 ft, making a total of 278 ft. No change to note since last report.

GRAND PRIZE AND ARGENTA.—East drift, 700 level, is in 300 ft and west drift 79 ft. North crosscut is in 56 ft. Crosscut towards foot wall in Argenta winze has reached the wall. Hanging wall crosscut is in 16 ft in favorable-looking ledge material; no wall yet. No trouble now with water, and everything is working well.

BELLE ISLE.—During the past week the north drift was advanced 12 ft through ground showing fine seams of ore, and presenting good indications for an ore chimney in the near future. The winze from the 250 level was sunk 25 ft in a favorable formation that shows small seams of ore.

NAVAJO.—The drift on the 450 level was advanced 14 ft the past week. The ledge shows a marked improvement both in size and the quality of the ore vein. On the 350 level, winze No. 2 was sunk 7 ft, and the material found continues to improve in character. Winze No. 4, which was sunk 10 ft, is also looking well. The usual amount and grade of ore is being produced by the stopes. The bullion shipment for the week amounted to \$15,686.18.

WILLOW CREEK DISTRICT.

SILVER WAVE MILL STARTED.—Cor. Silver State, Jan. 16: This day has been a notable one upon this side of the Paradise range. The resounding echo of a steam whistle for the first time saluted the primitive precincts of Queen river. For several years it has been apparent to those conversant with the facts that much merit belonged to the prospects on and about Willow Creek, but it remained for H. H. McColley and T. J. Harlan to render, by the building of a quartz mill, the demonstration of the fact. As to the merits of this camp, I will add that while no excitement prevails, and that there is no wish upon the part of any here to create one, there is already for the first run of this mill about 500 tons of ore from the Iowa mine that samples from \$20 away up into the hundreds. Your correspondent visited this mine yesterday, and found from the face of the tunnel, drifts north and south to the extent of 100 ft on the ledge, showing a 2-ft ledge all the way of good milling rock, say from \$60 to \$70 per ton. Many other properties are showing up finely. The Silver Wave mine, I am informed, is giving good

promise, assaying at the foot of the incline (30 ft) \$17.50 in gold and \$7.80 in silver. Another mine, the name of which I did not learn, is showing up well. It is the property of A. Shrewsbury, and he has several men at work. The claims of John Beran are worthy of mention, and so far as worked have produced a fine quality of ore. The Ohio mine is well known, and needs no mention. While its record is good, allow me to predict that many other properties in its immediate vicinity now in process of development will become as valuable.

Arizona.

STRIKE IN THE EDEN LASS.—Tombstone Republican, Jan. 16: The Eden Lass mine is located south of town about 3½ miles, directly on the center line of the great mineral belt that runs from Tombstone to the San Pedro river, 9 miles distant. It is on the western slope of a low ridge that lies to the west of Ajax hill, and is between a contact of porphyry with the lime. Its course is northeast and southwest, and can be traced for the length of 2 full claims. Two years ago this claim stood very high in the estimation of mining men. Nothing more than the assessment work has been done on it since then until quite recently, when a lease was given to some miners to work it upon tribute. At a depth of 85 ft a drift has been run for some distance in fair milling ore, the ledge being well defined. Coming up within 20 ft of the surface, they discovered a chimney of exceedingly rich ore—ore that is filled with greenhorn silver, with some black metal, assaying from \$1,000 to \$5,000 per ton. They now have out on the dump an amount of ore estimated at \$5,000, net value. They intend to drift to a point underneath this rich chimney, feeling confident that it continues down to that point at least, and how much further they do not know. This strike should have the effect of stimulating others to work their claims in the same locality.

Colorado.

DUMONT AND ITS MINES.—Colorado Miner, Jan. 16: Within a radius of 2 miles of Dumont there are 53 different mines that have produced more or less of the precious metals during the year 1882, and the amount will not fall but very little short of \$50,000. It is mostly gold, but silver has been found in some of the mines in paying quantities, and it is generally believed that the latter will predominate as greater depth is attained. Nearly all the ore that contained silver has been shipped to Georgetown and sold, while the gold ore has been worked up in stamp mills at that place or shipped to smelters in the valley. Among the most prominent mines are the Albro, Eagle, American Eagle, Ohio and Syndicate. Many other mines give good prospects, but the developments are too small to judge of their value. The two stamp mills, the Albro and the Mansfield, have been kept busy most of the past year on free milling ore. Dumont has improved but very little in the last year, although we noticed some new buildings in course of construction. The growth has been steady and healthy ever since the name was changed from Mill City to Dumont, and new buildings are only put up to meet the demands of the mining interest, which is the only industry.

Idaho.

THE SMOKY PLACERS.—Wood River Times, Jan. 17: The placer mining season generally lasts 5 or 6 months every year, or from the 1st of April to the 1st of October. Some years the season is much shorter. The snow is seldom gone before the middle of May, and by the middle of September the water freezes and it becomes impossible to wash gravel. The snow is 2½ ft deep in the Smokeys just now, which is a much lighter fall than is customary by this time of year. An open winter and early spring is expected. All the placer mining ground is now taken up—seven locations altogether. Messrs. Swift & McCarter intend starting up work early in the spring.

LITTLE LOST RIVER.—Wood River Times, Jan. 20: The mines are located on Little Lost river, in this county, 40 miles northeast of Arco, a stage station on the Blackfoot and Wood river road. The surrounding country is covered with lava. There is but one lode, the Tyndall, which runs north and south and dips to the west. The formation is rotten or decomposed quartzite, with trachytic dykes or crosscourses running through on the east wall. A peculiarity of the lode is that a 25-ft reef of pure white sandstone runs along the whole course of it in the vein. Wood and water are abundant.

Montana.

THE CABLE STRIKE.—Inter-Mountain, Jan. 20: The strike recently recorded in the Cable gold mine is one of the most important mining developments announced within the past year. Supt. Savery is averse to the publication of any facts relative to his company's operations, but in the interest of the mining industry of this territory it is deemed expedient to give the public some idea of what is going on in the old camp. Enough ore has been blocked out in the lower workings of the mine from the face of the tunnel to supply the 30-stamp mill for over a year. The ledge is 40 ft wide, well defined, regular and of uniform richness. A little more development will bring into sight an inexhaustible ore supply. The ore now being taken out averages in assay value from \$60 to \$75 per ton, exclusive of the gold nuggets which are frequently found in great profusion and of all sizes. Two weeks ago, it will be remembered, a piece of ore was extracted weighing about 150 lbs, and which was estimated to contain \$6,000 in native gold, most of it in nugget form. At present only 15 of the 30 stamps are in operation owing to the scarcity of water, but these stamps are daily crushing ore valued at \$100 per stamp. As soon as the water supply can be increased the daily product of the mill will be \$3,000, and this yield can be kept up for an indefinite period, as the ore now being treated is only of the average grade. This little 30-stamp-mill is thus making a wonderful record, and the product for this year promises to be over \$1,000,000, if only the ore in sight should be worked. The Cable mine could easily supply a 60-stamp mill. It is considered by all who know anything of its productiveness, richness and extent, a far more valuable gold property than even the famous Drum Lummion. It would take more than a million dollars in cold cash to buy it to-day.

New Mexico.

LAKE VALLEY.—Herald, Jan. 11: Work is progressing steadily at the Hillsboro mine, belonging

to the Black Range Co. The new find in the Superior improves as they work deeper into it, gaining both in extent and quality. In the Bullion the drift has opened into the vein as anticipated, and they are preparing to do considerable stoping. Quite a large body of very rich ore will be taken out as rapidly as possible. The trouble at the Brilliant mine with the employees is all over and a full new gang of men are now at work sinking a shaft, and timbering it thoroughly as they go. This is the mine belonging to Jefferson Reynolds, of Las Vegas. Ten or fifteen thousand dollars' worth of work has been done on the Iron King mine, 1½ miles from Kingston. It has two shafts 8 ft deep and various crosscuts. There are copper carbonates and manganese oxide. The Kentucky mine has 50 tons of fine ore on the dump. In the tunnel there is a 6-ft breast of ore which runs high. There is also a shaft 20 ft deep. On the surface are crop-pings which indicate a very rich mine. The ore is a kind of carbonate. Moore Bros. & McDougal are at work on the Oxford, an extension of the Brilliant, going down on the iron croppings with the intention of crosscutting toward the quartzite. There is an immense vein on the claim, which carries mineral on the surface assaying 42 ozs. Sawpit canyon is showing up some very fair properties, some of them indicating galena which will be valuable for smelting. The Jack-pot, Mountain Maid, Lone Boy, and Yellow Jacket are among those that have been fairly tested by their owners and promise well in future development. Gold in considerable quantities is found on the south branch of the north Percha, in the vicinity of the Solitaire. A pan of dirt showed several colors. This gold placer working, however, will not prove a success in this district, but the fact that the colors are found is important, as it indicates that gold lodes will yet be discovered higher up in the mountains. Work is in progress on the Miner's Dream, which is a very valuable lead. There had been some anxiety on account of the scarcity of lead in the district previous to the recent strikes on this mine, when ore carrying lead in large quantities was discovered. This will avoid the difficulty to some extent, and indicates that there is plenty of lead in camp for fluxing. The "Kentuck," situated in the mining belt in which is embraced the Illinois, Andy Johnson, Brush Heap, United States, Clipper, Good Will and Black-eyed Susan, is developed to the extent of 30 ft in a body of mineral, which is galena, copper carbonates and bromide of silver. The Kentuck only needs to be worked to become valuable to its owners.

A FRAUD.—New Southwest, Jan. 13: In a certain mining district, not a thousand miles away from Deming or Silver City, there is said to be a stock company operating in a very darkish kind of a way. The capital of the corporation is nominally \$400,000. It has ground a distance of about one mile up the side of a steep and rugged mountain. Its agent has sunk two shafts, one 75 and the other 60 ft in depth, sunk in granite—solid granite and in nothing but granite. It has one tunnel in the side of the rugged hill aforesaid for the distance of 75 ft and another 30 ft, out of both of which comes some nice granite. The company employs a superintendent and six men, and instructions were recently received from the East to sink a 600 foot shaft—again we suppose in granite. Parties who have been on the ground say that there is not a trace of metal of any kind in any of the shafts or tunnels, and yet the work of sinking—in granite—goes bravely onward. Work has been commenced on several of the mines at Tres Hermanos, and very favorable reports from them have been received.

Oregon.

SNOW.—Jacksonville Times, Jan. 16: A considerable amount of snow lies back in the hills, upon which the miners anticipate fondly. Wm. Heeley was down from big Applegate this week, who informs us that the Chinese operating the Applegate Gravel Co.'s claims have suspended work. H. D. Russell has sold his interest in the McKee claim on Jackass creek to Polk Dews. W. Q. Brown, superintendent of the nickel mine on Cow creek, is having a wagon road built to G. W. Riddle's old place from the mine. The O. C. and S. mining company, at Oakland, Or., have discharged all the miners, and for the present work in the mine will be discontinued, as they already have ore enough out to run the furnace four months. The last clean-up was 38 bottles of quicksilver. J. F. Salmon, one of the inventors of the quartz mills now being operated at Blackwell and Horsehead, has recently been putting them in running order. They come up to expectations now, and are said to be unexcelled in the economy and perfection of their work. Mr. S. is interested in a hydraulic claim on Cow creek, which has not been worked to any extent this season, owing to the weather. There are two like claims in that vicinity.

Utah.

BARREE & WALKER.—Silver Reef Miner, Jan. 18: Although this property has been encumbered for some time with suits and attachments for debt, we have no hesitancy in saying that at no great distance in the future, affairs now somewhat muddled, will give way to a more favorable impression, and at least no one suffer from loss who has had dealings with this company. At present the property and mill are closed down and undoubtedly will remain so until it changes hands.

STORMONT.—This property is being worked with satisfactory and flattering results under the able and energetic management of Col. Allen. From 10 to 12 teams are engaged in hauling the ore from the mines to the mill on the Virgin river, a distance of some 5 miles, and kept constantly at work. About 35 or 40 tons of good grade ore is crushed daily. The mines are looking better and richer as depth is attained, while development is kept moving in the various shafts, levels and drifts as time and opportunity present. Bullion shipments are regular through McCormick & Co., of Salt Lake.

CHRISTY.—The vast and inexhaustible deposits belonging to this company still improve at each step of development in extent and quality. In a short article for the press one can only get an idea of what the property embraces, or its immense bodies of ore, workings, and so on. To get a proper understanding of these facts necessitates a visit and examination of the underground workings. The Christy Co. has expended thousands and thousands of dollars in opening and developing its mines, which, by the way, has been the boon of success it now enjoys.

Substances Used in Amalgamating.

The application and modification of the amalgamation process, as practiced on the Comstock, has occasioned among experienced millmen great doubt as to the beneficial results derived from the use of any chemical agents at present mixed with the ore. This doubt is occasioned, or at least strengthened, by the custom of late years of decreasing the quantity of salt and sulphate of copper added to the charge, without apparently diminishing the product of bullion. Many amalgamators now abstain from the use of both reagents; others add a small quantity of sulphate of copper, but no salt; in a few instances the custom is to throw in only a little of the latter, while in many mills the rule is to employ a small amount of both substances, owing to a slight prejudice against the abandonment of "chemicals" altogether.

The action exerted by these two reagents in the pan would appear clearly to indicate that the benefits derived from their use are partly to aid in converting the sulphide into chloride of silver, as in the patio, and partly to decompose such minerals as are but slightly attacked by the mercury. In the Comstock process, however, the large quantity of iron present must tend greatly to produce sub-chloride of copper almost as soon as the chemical agents are thrown into the pulp.

Notwithstanding the importance of common salt and sulphate of copper in the patio, and, under certain conditions in the pan, their value must be considered as only secondary in the decomposition of a large proportion of the Comstock ores. The advantages derived from their use are shown to be exerted chiefly upon such minerals as blende and galena, which are but slightly attacked by the mercury. But the amounts employed are in most cases too small to effect any favorable results. On the other hand, if a sufficiently large proportion of the reagents are consumed in the pulp, in order to produce the beneficial returns, it is always at the expense of preserving the necessary purity of the mercury. The quantity of salt deemed necessary by millmen varies from one-quarter of a pound up to seven or eight pounds per ton; scarcely any two establishments have the same rule.

The consumption of sulphate of copper also depends upon the ideas of the amalgamators, but the amounts do not differ so widely as in the case of the salt. It ranges from one-quarter of a pound to three pounds per ton.

The addition of the sulphate without salt is of late years a common practice. The opinion among those who work their ore in this way is that it gives a little better yield than when mercury alone is employed, particularly where the ore indicates the presence of galena in any considerable amount, in which case it is said to "quicken" the mercury and render it more energetic.

Continued experience appears to determine this fact with a considerable degree of certainty. In working ores containing only a small percentage of lead, the quicksilver very soon becomes dull and inactive, or, as it is technically termed, it "sickens," and the yield from the pan is consequently low. Lead is one of the most deleterious metals in destroying the amalgamating energy of mercury, and at the same time is very rapidly absorbed when the two metals are brought into contact. Sulphate of copper possesses to a certain extent the property of expelling lead from the mercury, copper being amalgamated and sulphate of lead formed at the expense of the sulphuric acid of the copper salt.

If a concentrated solution of sulphate of copper be allowed to stand upon the lead-amalgam, the action takes place quite rapidly, mercury containing lead acting much more energetically upon the copper solution than when perfectly pure.

This salt, however, does not appear, under any circumstances, to possess the power of completely driving out the lead.

Another advantage derived from the addition of a small quantity of the sulphate of copper is that mercury, under certain conditions, when exposed to the solution, forms a minute amount of copper amalgam, which causes the metal to act with a somewhat greater intensity in the decomposition of the silver sulphide than when perfectly pure. Iron, as a reducing agent in the pan process, probably plays an important part

in bringing about the favorable results obtained. This may occur, according to Mr. Hagne, in three ways:

First—It aids in a great measure the decomposition of the chloride of silver.

Secondly—It reduces the calomel formed during the operation; the chlorine, combining with the iron, goes into solution, and the heavy metal is liberated. In this way it not only prevents a chemical loss of mercury, but also serves to keep the surface of that metal bright and clean, which otherwise might be coated with a thin film of sub-chloride, which would greatly destroy its activity.

Thirdly—It undoubtedly assists directly in the amalgamation where the two metals are brought into close contact with the easily reducible sulphurets. The successful and continued operations on the Comstock without the aid of any other chemical agents sufficiently prove this statement. The experiments in treating argentite and iron filings with mercury confirm the fact.

Humboldt, in speaking of the amalgamation problem in Mexico, draws attention to this point, and remarks upon the rapidity with which amalgamation was secured when the two metals were triturated together with argentite. This action of iron is obtained not only from the constant agitation maintained, which brings the pulp and metal in contact with the sides and bottom of the pan, but also from the amount of iron disseminated in a fine condition through the ore, produced by the wear of the stamps, shoes and dies.

Plumbago.

Plumbago is an instance in which a variety of uses have been discovered in modern times for an article well known for several generations. Chemically, pure plumbago is a form of carbon, and the chemist knows it as graphite. Popularly it is known as black lead from its metallic lead gray luster. It is still further known as "kish," by workmen, when it occurs among the crystals of rich pig iron. Its specific gravity between 2.09 and 1.8. It feels very unctuous to the touch when rubbed between the fingers. Plumbago neither melts, softens, nor is in any way changed by the temperatures, provided access of oxygen be prevented, and it burns very slowly when heated in atmospheric air. On account of this property, it is a valuable material for making crucibles. As it is not of itself plastic, it is mixed with refractory clay in sufficient proportion to produce a material capable of being molded into crucibles on the potter's wheel. Good plumbago crucibles support sudden alterations of temperature without cracking, and may be used after being repeatedly heated and cooled. The graphite or plumbago on the outer surface will ultimately burn away unless protected by dipping in a mixture of clay and water containing borax in solution.

A few years ago the only uses to which plumbago was applied was in the manufacture of black lead pencils, and for the domestic cleaning of household grates. Afterwards its use as a lubricant for heavy machinery was discovered, and it is now largely used for the bearings of water wheels and other large gear, and as a lubricant for gun carriages, and for blowing cylinders of blast engines. It is peculiarly suitable for blowing cylinders, as it is nonflammable. It is free from the clogging properties of oil, and as dust is frequently drawn into the blowing cylinder, oil soon clogs, rendering constant supervision necessary. Plumbago is also used for lubricating piano keys, the pivots of large clocks, etc., and particularly for wooden cog wheels.

The most famous mine in England is at Borrowdale, in Cumberland; but plumbago is found also in India and Ceylon, in the United States, Canada, Nova Zembla, Australia, in France, Sweden, Russia, and a few other places including Bohemia, where there are large mines. The development of the steel trade has largely increased the demand for plumbago, the large works of Krupp & Co. alone using upwards of 200 tons annually.

Another increasing use of this valuable material is for foundry's blacking, which is used as a facing powder for sand molds by thickly dusting it over the molds, by shaking a bag in which is a quantity of finely powdered black lead. The facing powder is said to need no smoothing after dusting, and does not run before the hot metal. It is used in a similar manner for the molds of chill castings; it is also used to coat the molds of lost castings as a thick paste. It is further useful for coating patterns—if of wood it is rubbed on dry; if the patterns are of iron it is painted or rubbed on with a brush. Another use in the foundry is to throw it on the surface of hot metal whilst in the ladle to prevent too rapid cooling, and for which purpose also a wash is painted on the coating of the ladle, as the plumbago is practically unflammable. There are no sparks, and castings that are from molds, dusted with this mineral, have a fine blue skin.

Of course, plumbago, like other minerals, is never found pure, the impurities being silicon, oxide of iron, alumina, lime, magnesia, etc., according to the localities in which it is found.

To purify it, after being powdered, it is washed and sifted into different degrees of fineness. One of the latest applications of plumbago is in the manufacture of paint. It is peculiarly adapted for withstanding the effects of the weather and salt water, for which reason it has been largely used for painting ships, piers, bridges, tanks, buoys, tarpaulins, railway trucks, etc. Its great body enables it to cover more surface than an equal weight of most paints. At present the only colors which have been manufactured are black and chocolate. It is used for glazing gunpowder, for coating ships and boats to prevent weeds and barnacles adhering to the bottoms, and for dusting steel ingot molds.

Artificial graphite is now made so that the supply is not so dependent upon natural sources as formerly. — *Manchester (Eng.) Mechanical World.*

Bad Mining Management.

Of all the evils that our country is afflicted with, the worst is that of having a quartz mine fall into the hands of Eastern capitalists, or rather Eastern stock gamblers. After a thorough trial of this style of mining, and after watching the results for many years, we are confirmed in the opinion that nothing worse can befall a mine—as far as this country is concerned—than to have it fall into the hands of that class of operators. A good property undeveloped is put into the Stock Board of New York, for instance. The agents to give it a "gilded send-off," convey the idea that it is a perfect wonder and rich beyond compare. They say that all that it needs is just enough capital to start up the mine and mill, and that wonderful dividends will result. Acting on these representations Eastern men put their money into the stock, and in a very short time commence to clamor for the promised dividends. Probably not half enough money has been furnished to develop and improve the mine, and our own people, merchants, farmers and contractors, are holding claims for the half that has not been advanced. And here is where the bad management comes in. Instead of using the proceeds of the mine to pay their debts and make further developments until it is on a substantial footing, the money taken out is shipped to New York and distributed in the shape of dividends with a grand flourish of trumpets, to satisfy the demands of rapacious stockholders and bull the market, and in the meantime our own home people are left to bear the brunt. They must wait, because the property is here, and they are interested in "keeping up the country." Operations are worked along in this way for a while, the mine—which may be a good paying property—is only half worked and does not have half a chance, and then some creditor, who has "packed" it as far as he can, is obliged to bring suit for his money, and the whole business ends in a grand collapse, the mine is condemned, and other valuable properties in the neighborhood suffer because of the failure. The whole system is wrong, and it is a curse to any mining country in the world. When a failure is made in this manner, it is more than an even bet, every time, that a California company of mining men can take the same property, put it in shape, and make it a good dividend paying mine. They know what mining means, and know that it takes time and money to put it on a good footing, except in an exceptional case, now and then, where a perfect bonanza is found, which can be made to pay at once. Mining is a business which needs both brains and experience, and when men with a very small stock of these qualifications are placed in charge, it does not take a wise man nor a prophet to predict that failure is to be the result. — *Plumas National.*

New Method of Separating Minerals.

Mr. T. Buettgenbach contributes to the *Berg und Hüttenmännische Zeitung* the following: The separation of intimately intermixed minerals from each other has hitherto been effected mainly by taking advantage of differences in density, structure or capacity for being rendered magnetic by calcination, while no use has been made of the striking properties evinced in differences of specific cohesive strength. The separation of minerals of unequal hardness, and by reason of their greater or less susceptibility to break down into fragments of different sizes, is not possible with the ordinary crushing or stamping mill; but it is different when the mass is thrown violently against a hard resisting surface, in which case, if the velocity is properly proportioned, only the more brittle substances are broken. In order to obtain a proper separation of iron pyrites and zinc blende, the author has been led to experiment on the use of Vapart's centrifugal breaker, not only as a crusher, but as a separating machine. When this apparatus is driven at 800 revolutions per minute, lumps of iron pyrites of 20 to 25 millimeters diameter are reduced partly to dust and partly to grains of 1 to 1½ millimeter; but when the velocity is reduced to 400 revolutions they are scarcely touched. Blende, which is of inferior hardness, is reduced to the finest fine stuff at 800 revolutions, while at 400 it leaves the apparatus partly as dust and partly as grains of 0.5 to 3.0 millimeters, in diameter. If, therefore, a mixture of the two minerals is treated at the low speed of 400 revolutions per minute, the pyrites are almost entirely unaltered, while the blende, being very finely reduced, may be separated by a simple sifting process. In order to make the process continuous in action, the crushed ore is passed through

a hopper into a drum sieve making nine and two-tenths revolutions to every hundred of the mill, and divided into three parts with holes of 1, 2 and 3 millimeters respectively. The coarser stuff passes into a second drum with two divisions, having holes of 6 and 8 millimeters respectively, which is driven at eight revolutions per 100 of those of the crusher. The size of the sieve holes depends upon those of the particles operated on, and it is important that these shall be as nearly uniform as possible. The operation may be carried on wet or dry, but in the latter case it is essential that the material shall be as free from moisture as possible, as the powder, if damp (with about four per cent. of water), binds, and easily stops up the holes in the sieves. The dust is also a very great inconvenience, which, however, may be remedied by the use of a small jet of water. The separation of the two minerals is not completely effected, as the angles of the grains of pyrites are apt to break off, even at moderate speeds of the machine, and to become mixed with the fine blende; but it is sufficient for ordinary commercial purposes. The economic value is shown by the following calculation: Mixed ores with equal contents of blende and pyrites are worth at the utmost about 10s. per ton, and are not easily disposed of at that price; but when subjected to the treatment described above, the products are 11 cwt. of pyrites, with 5% of blende, worth 9s. 6d., and 9 cwt. of blende, worth 31s. 6d., or a total of 41s. for the separated products. Taking the cost of the raw material at 10s., and the working cost at 9d., the profit on the process appears to be 30s. 3d. per ton of stuff treated. The amount of material that can be crushed in a Vapart mill is about five tons per hour passed once through, so that a single apparatus will be sufficient for even a very productive mine, as mixed ore of this kind never forms more than a comparatively small portion of the total produce. H. B.

Some Reactions of Titanium.

The following "Notes on Some Reactions of Titanium" were submitted at the Colorado meeting of the American Institute of Mining Engineers by Mrs. Ellen H. Richards, of Boston, Mass.: It is of importance to analysts to have a ready means of detecting the presence of small quantities of titanium in iron ores, and in certain fluxes and slags. The method given in Elderhorst's *Blowpipe Analysis* (fusion with potassium hydrogen sulphate) requires considerable practice in order to regulate the heat that the titanium oxide shall become soluble.

In Brush's *Determinative Mineralogy* is found a method which, at least in inexperienced hands, has given better results, i. e., fusion of the substance to be tested with soda on charcoal in the reducing flame. The solution in hydrochloric acid of the bead thus obtained, boiled with tin or zinc, gives the characteristic violet color; but when the mineral contains less than four per cent. of titanium oxide, long boiling and consequent concentration is necessary. In fact the test would seem to be much less delicate than is generally supposed.

In the course of some analyses I quite accidentally found that a peculiar color is given to tumeric paper by solutions of titanium chloride. This color is hard to describe, being modified by the quantity of ferric chloride present in the solution; but it is neither the orange of zirconia nor the red of boron. It is rather a dull shade of purple, and is easily recognized when the paper is dried, although the color fades in a few hours.

By this means a solution containing .015 per cent. of titanium oxide can be easily tested. The same solution, treated with tin, required to be concentrated to one-tenth its bulk before a decided color could be obtained.

The color on tumeric paper is intensified when the solution has been treated with tin and has failed to show a shade of color. This and some other indications show that the best shade of color is given by the titanous chloride rather than by the titanic chloride, and no other salt of titanium has been found to give the color.

Another peculiar property of titanium salts has come under my observation. When titaniferous minerals are soluble in nitric acid, and the solution is subjected to the action of the battery, the soluble titanium is converted into the insoluble oxide and appears on the electrode, in some cases as a white coating; this coating interferes with the estimation of copper, as it is deposited along with the metal, sometimes to the extent of one per cent. of the copper.

In the course of the experiments it was found that a strong battery current reduced the titanic oxide to titanous oxide in aqueous solution, obtained by fusion with potassium hydrogen sulphate in acid solutions of the oxalate and sulphate. The oxalate, in particular, soon became a deep golden yellow, and after 36 hours, although the solution was clear, the addition of ammonia produced a precipitate of a beautiful deep blue color.

THE NEW WIRE GAUGE.—The Board of Trade have issued a circular to those interested in the new standard wire gauge, which is shortly to be legalized, accompanied by a copy of the new standards, and asking the opinion of manufacturers. The Board of Trade does not propose to make any change in the smaller gauges from 20 to 50 BWG, but the sizes of the Nos. 8 to 19 are reduced in the new standard. The wire-makers of Warrington and Shropshire are surprised to find that the Board of Trade has remodeled the gauge on a plan of its own, irrespective of their expressed views.

Tellurium in Copper.

At the Harrisburg meeting of the American Institute of Mining Engineers, T. Eggleston, Ph. D., of New York, read the following paper:

Some months ago samples of black oxide of copper and of pig copper from Colorado were sent to me to examine for arsenic and antimony. I examined them both by the blow pipe, and in the wet way, but found none present.

A quantity of this material was purchased by a large metallurgical works, but when they attempted to refine it they pronounced it to be full of arsenic and antimony; so much so that their furnaces were, as they said, "poisoned," and rendered unfit for refining. I then re-examined the samples, and, at the same time, some of the material which had "poisoned" the furnaces, and found no traces of arsenic or antimony when the usual amounts for analysis were used; but on taking very large amounts I found traces merely, in some parts of the sample, but not in all. As it was a matter of interest to ascertain what the white substance that "poisoned" the furnace was, I sent to the works making the black copper, and obtained some of the matte from which the black copper was made. I took careful samples, both of it and the black copper and the refined copper. I then found the impurity to be tellurium, a substance not heretofore known as occurring in copper. I give below one analysis of the matte, two of the black, and one of the refined copper.

	Matte.	Black Copper.	Refined Copper.
Copper.....	55.02	97.120	98.090
Gold.....	0.06		
Silver.....	0.40	0.132	0.128
Lead.....	17.57	0.777	0.757
Zinc and nickel..	2.22	0.070	0.100
Iron.....	4.18	0.130	0.080
Sulphur.....	20.02	0.236	
Tellurium.....	0.12	0.003	0.007
Arsenic.....		0.006	0.001
Slag, etc.....		1.270	0.102
	99.80	99.834	99.414

*No traces were found with the blow pipe.

The mattes and the black copper are results of the treatment of copper ores with the tellurium ores of Colorado. In the laboratory no traces of white fumes were shown on charcoal, but when the metal in the furnace was subjected to the process of "dry roasting," as was unintentionally done, very dense white fumes were given off. When refined and cast into cake, it had the ordinary appearance of cake copper. It was then reheated for rolling in the ordinary way, showing no signs of impurity. At the first pass in the rolls, very fine cracks showed themselves, which opened in succeeding passes. At a thickness of about 0.03 meter the cracks on either side nearly penetrated the cake, and at about 0.008 meter it began to fall to pieces. It was heated and rolled at different temperatures, but always with the same result.

When cold the metal is tough and malleable. Although the cakes in the molds showed no coating, when they were heated repeatedly and allowed to cool in the air they became covered with a white powder, which proved to be the oxide of tellurium. The copper, as it comes from the cake molds, has every appearance of being good copper.

This is the first time, so far as I know, that the presence of tellurium has been detected in commercial copper. But very little of it is removed in the treatment, as the four analyses show.

It is surprising how very small a quantity renders the copper red short, and consequently worthless for rolling.

The following rates of passage have been adopted over the Southern Pacific Railroad from San Francisco, via El Paso, San Antonio and Houston, to New Orleans: For first-class tickets with stop-over privileges, \$98.50; second-class tickets for a continuous trip, \$80; third-class tickets for a continuous trip, \$55. The following named rates are now in effect for passage by rail from New Orleans, La., to New York City, N. Y.: For first-class tickets, unlimited, according to route, \$53.50 to \$45.35; first-class tickets, limited and for continuous trip, all routes, \$38; second-class tickets, limited and for continuous trip, all routes, \$32.25; third-class tickets, limited and for continuous trip, all routes, \$24.50.

UNDERGROUND TELEPHONE WIRES.—The *Engineering and Mining Journal* says that "there is a good deal of unreasonable agitation in regard to putting telephone wires underground, and the legitimate and feasible plan of subterranean telegraph cables, at least in cities, is assumed, without any knowledge of the facts, to be applicable to telephone wires also. We are assured by practical electricians of high authority that it is impossible to work underground telephone lines under the conditions prevailing in our large cities, and any steps to secure by legislation the removal of the wires from our streets should, so far as they affect telephone lines, be preceded by an inquiry whether or not it is at all possible.

SUICIDE.—Seventy-two persons committed suicide in San Francisco in 1882, from these causes: Intemperance, 22; poverty, 15; temporary insanity, 11; financial embarrassment, incurable disease, physical suffering, six each; domestic trouble and fear of arrest for crime, three each; business disappointment and disappointment in love, two each; jealousy, one.

The Mint at San Francisco is the largest in the world—twice as large as the one in Philadelphia, and three times the size of any in Europe, having \$24,000,000 worth of coin and bullion stored away in its vaults.

USEFUL INFORMATION.

LUMINOUS PAINT.—Balmann, in his luminous paint, succeeded in obtaining a composition that was a great advance on that of Canton and Becynrel. He combined it with a varnish that resisted atmospheric influence, and despite many attempts in the same line, this process has not been surpassed. The great difficulty in making these colors is to have the exact chemical proportions. There must also be an excitant—sunlight, or electric or magnesium light. Water has no effect on it, and the luminous paint produces the same color, no matter what may be the color of the light employed for charging it, only it becomes whiter after a time. Chlorine, muriatic acid and nitric acid destroy the luminous power, and iron and lead substances interrupt it. If this property could be applied to colors it would be of great practical value, but it would depend upon two questions being solved: Whether such preparations would retain this luminousness, and for what length of time; and secondly, whether the luminosity could be preserved when mixed with an adjunct for painting purposes? In this case linseed oil varnish would be necessary for objects exposed to the air, and the preparation would be exposed to the effects of the air like any white oil color, not to mention that the varnish would turn yellow and gradually destroy the luminous force. A firm in Dresden is said to produce a pure white luminous paint. There is, doubtless, a large field for inventors.—*Oil and Paint Review.*

PRINTING ON WOOD.—A machine for printing box sides and ends, instead of stenciling, and doing the work ten times faster than can be done by hand, has been patented by Connell & Dengler, of Rochester, N. Y. It has the advantage of rolling in a very rapid and clear manner all cards or trade marks much more perfectly than can be done by hand, thereby rendering it of great importance to the merchant or manufacturer. The type or form is cast in brass, and secured in such a manner that it can be easily and rapidly adjusted to print upon the board at the proper time. The inking rollers can be instantly raised from the type to prevent inking when the machine is not fed with boards. It will print boards varying from $\frac{1}{8}$ to $1\frac{1}{2}$ inches in thickness, and at the rate of 1,500 to 2,000 impressions per hour. The boards or sides of boxes are introduced to the machine in quantities of ten to twenty pieces at a time, and the bottom piece of the pile is fed by a reciprocating bar to its proper place in order to receive the impression at the proper time, the boards above dropping down to be fed in like manner until all are printed.

AMERICAN AND ENGLISH HOUSE-BUILDING.—The editor of the *Builder and Woodworker* says: The modern London house is a surprise to Americans. If one take the pains to go through 500 or 600 South Kensington houses, all built within the last two years, vacant, and kept in stock for future buyers, he will not take kindly to the way in which English mechanics do their work. Floors are badly laid; strange to say, there is a general shrinkage in the wood-work, indicating the use of unseasoned lumber, and the hardware is of a quality that is never used in this country, except in houses of a very cheap class. The English builder seems to think that almost any kind of hardware will answer, so he uses locks that in six months or a year are a source of constant vexation. To make matters worse, the work of adjusting hardware to its place is badly done; doubtless the result of piece-work at low prices. These remarks apply to houses that are held at a valuation of \$100,000, and on leased ground, and the writer does not speak from hearsay, but from observation.

TEMPERING LOCOMOTIVE SPRINGS.—In regard to the correct method of tempering locomotive springs, a contemporary says: I will give a recipe, and one that has been tested and is now in use in a number of railroad shops. The materials to be used are as follows: Eight ounces gum Arabic, four ounces oxalic acid, two pounds fine salt, two and one-half pounds brown sugar and 15 galls. whale oil. Heat the leaves of the spring red hot, but not so as to burn or overheat. Plunge into the mixture and let lay until cool. In using the above mixture it will have to be employed in an iron tank. The best method for testing a spring is to put it under a locomotive and let it be used practically. If it is not tempered properly it will soon show evidence of it.

SAWDUST INSTEAD OF HAIR.—It is said that sawdust is better than hair in protecting rough cast from peeling and scaling under the influence of frost and weather. The sawdust should be first dried and then thoroughly sifted, in order to remove the coarser particles. A mixture is then made of two parts of sawdust, five parts sharp sand and one part cement, which should be thoroughly stirred together and then incorporated with two parts of lime.

TO PRESERVE HICKORY TIMBER.—The *Hub* says that a thorough dosing of hickory timber with raw turpentine is a preventive of the ravages of worms, and one of its correspondents says that this will destroy worms already at work in the timber. Carriage makers whose valuable stocks of hickory are being injured by pests will find this worth a trial, at any rate.

EDGE TOOLS.—There are many times when it is very desirable to have the edge of a tool preserved, as in the case of boring a cylinder, milling-cutters, gear-cutters and similar standard tools, but I think it may be safely said that there are not half enough grindstones worn out in any machine shop. Then an oilstone is a good thing. Many suppose an oilstone is only intended for carpenters and pattern-makers, but I find a turning tool will hold an edge much longer if nicely whetted, and besides, will do a better job. Every lathe should have an oilstone.

The longest line of fence in the world will be the wire fence extending from the Indian Territory west across the Texas Pan-Handle, and 35 miles into New Mexico. We are informed that 85 miles of this fence is already under contract. Its course will be in the line of the Canadian river, and its purpose is to stop the drift of the Northern cattle. It is a bold and splendid enterprise, and will pay a large percentage on the investment. The fence will be over 200 miles long.

BRICKMAKING WITHOUT BAKING.—Equal parts of hydraulic lime, sand and scoria are pounded and then mixed, being made into a paste by the addition of water. This paste is submitted to strong pressure in molds, and afterward hardened in cold water. The bricks, therefore, it will be seen, consist of hydraulic cement.

GOOD HEALTH.

A Marvel of Surgery.

The Philadelphia *Record* relates the following remarkable case of surgery, in which a man has been breathing for five years through an opening in his throat. We quote as follows: The students in the Hospital of Oral Surgery, at Tenth and Arch streets, were shown a patient at Saturday's clinic whose throat had been cut from ear to ear, and who had then been hanged by the neck, but still survived his injuries. He breathes through a silver tube in the throat, and for six months was nourished entirely by enema.

The man's name is Simon Ladenski, a native of Roumania. In the winter of 1877—he then being 23 years old—Ladenski was one of a party of 10 men whose throats were cut by a band of gypsy robbers on the road from Varsloe. Ladenski was not killed, and on regaining consciousness and finding the robbers quarreling over the division of the plunder, he attempted to crawl into some bushes by the wayside. Being detected, he was strung up to a tree by the neck, and when again unconscious he was let down and thrown among the bodies of his companions, but not until he had been stabbed in the abdomen and cut in the cheek. Two days later the bodies were found by Prof. Russ, of Jassy, and Ladenski and a companion who was still alive were removed to town. The latter soon died, and then Prof. Russ removed his patient to Vienna. There Ladenski was placed under the care of the most eminent Austrian surgeons. It was found that the windpipe was closed, and for two years the man was unable to utter a word. He breathed through an opening in the neck. After many efforts a large threaded needle was passed up through the trachea and into the mouth. Small beads were then drawn through, being daily increased in size in order to effect a permanent enlargement of the obstruction. The man is still obliged to practice this device, and wears the instrument in his windpipe during the night, being able to breathe when in an upright position without aid. He has been examined by the leading surgeons of Berlin, Paris and London, and it is expected that some day it will be possible to close up the opening in the throat.

Face Ache.

Half the human race perishes before its time for the want of a little knowledge of the rules that govern health. The beginnings, the nuclei, are few, from which radiates the hosts of diseases that afflict mankind. It is important, therefore, that everyone should know what mischief may come from neglect of things seemingly trivial. As an example, let us trace the possibilities connected with that very painful, but very common ailment, toothache. The intense pain is caused either from an inflamed condition of the membrane that lines the tooth socket, the tooth being sound, or else from decay in the tooth itself, which has extended to the nerve. In either case we have inflammation of the membranes and nerves that are encased in unyielding channels of bone; hence the severe pain, followed by death and decay of the parts affected. While it would, as a rule, be unwise to resort to radical means to cure the trouble during the inflammatory stage, it is positively unsafe to neglect those means when the pain and irritation have subsided, for the *truce* is usually but temporary. If the decay extends to the surface of the tooth, the cavity forms a sort of safety valve for the escape of the dead matter, thus postponing or preventing more serious symptoms. But if the teeth are apparently sound, and there is neuralgia of the face, head, neck or shoulders, it is certain that the teeth are not sound, and that an expert dentist will find minute cavities extending from the crowns to the fangs of some of the teeth, or else ulcerative points at the extremities of the fangs themselves. The remedy, of course, is to properly fill every cavity, being careful to make a

minute examination, so as to miss none. In all recent cases this is a radical cure. Should that course fail, it is certain the disease has extended beyond the reach of that remedy, and however sound appears the offending tooth, it must be removed, and the removal of teeth must continue until they are all gone, if found necessary to check the neuralgia. There are, unfortunately, neglected cases where these methods are unavailing, and where the surgeon follows the disease to the cavities of the jaws, sawing through the bone and taking out the dead portion of the nerve; and still there are depths beyond the reach of human skill, where the sufferer writhes in pain until death comes to his relief; for a diseased tooth may be the beginning of fatal nervous diseases, and of dyspepsia and blood poisoning. We trust this article will be carefully read, for it points out the cause and the remedy for a class of diseases that produce more intense suffering in the world than all other diseases combined.—*Journal of Health.*

Long Life.

The subject of longevity is always one of great interest to everybody. "Live forever" is a favorite salutation in some countries. In the old times people found great delight in imagining their heroes gifted with continual life and un fading bloom of youth. With what breathless interest one follows Ponce de Leon as he plunges into the wild forests of Florida in the fruitless search for the fabled fountain. With the advance of civilization and the scientific study of disease and medicine and the better understanding of sanitary conditions and laws, there has been a steady increase in the average life of the individual. Governments are studying how best to promote length of life. Those who lead sober, peaceful lives, free from all great troubles and strong excitements, are surest of the coveted length of days.

Some time ago the French Government sent a circular letter to all the districts of that country to collect information as to those conditions of life which seemed to favor longevity. The replies were very interesting, but on the whole rather monotonous; the general result was that longevity is promoted by great sobriety, regular labor, especially in the open air, absence of excessive fatigue, easy hours, freedom from galling poverty, a philosophical mind in meeting troubles, not too much intellect, and a domestic life. The value of marriage was universally admitted, and long-lived parents were also found an important factor. A healthy climate and good water were mentioned. All this agrees with common sense, unless the idea that the intellect is a hindrance to longevity be considered unreasonable, and we know that some of the most intellectual men have lived to a great age.

Interesting researches concerning the comparative longevity of men and women in Europe have recently been made by the Director of the Bureau of Statistics at Vienna. From these it appears that about a third more women than men reach advanced age. This seems corroborative of what was said above. Women offend rather than men lead quiet, regular lives. They have fewer bad habits; are less exposed to strong passions and excitement.—*Potter's Monthly.*

Value of Asses' Milk for Children.

In the Paris Academy of Medicine, M. Parrot has recently called attention to some remarkable results obtained in the Hospital des Enfants-Assistés of Paris in feeding delicate infants with asses' milk. Many of the infants in that hospital have diseases which forbid their being suckled by nurses (whom they would soon infect). Hence, the feeding bottle was formerly used for them; but, spite of great care, the endeavor to foster the small vital force of these children was of little avail. Direct application to the udder of an animal was then tried. At first the infants were thus fed with goats' milk, but it was soon found that asses' milk was greatly preferable, and all are now fed with that, one, two, sometimes three infants being held to the animal's udder at once. The nurses do this with great ease. During six months eighty-six infants having congenital and contagious diseases have been treated in the hospital nursery. Of the first six, fed with cows' milk on feeding bottles, only one was cured. Of forty-two fed at the goat's udder eight were cured, while thirty-four died. Of thirty-eight fed at the asses' udder, twenty-eight have been cured, while six have died.

The virtues of asses' milk have been appreciated some time in France. For many years Paris and the large towns have been visited every morning with troops of the asses, brought in to supply their milk for invalids. It is said the use of the milk was introduced by Francis I., who, reduced to a very weak state and a despair to physicians, was induced by a Jew from Constantinople to take asses' milk, and thereby got well again. This milk has much less of plastic matters and butter than goats' or cows' milk, and is easily digested. M. Parrot notices the practical advantage in the ease of suckling from the ass, in that the animal is so easily fed; it is content with the poorest fodder. The goat suffers from a diet that lacks variety, and in the city its milk is not what it is in the country. The asses kept at the hospital referred to are in stables adjoining a field, in which they generally pass part of the day. It may be mentioned, in fine, that weekly statistics for Paris have lately presented the unwonted fact of an excess of 200 and 240 births over the deaths.—*London Times.*

TABLE OF CONTENTS.

EDITORIALS.—Locke's Improved Lead Smelting
Furnace; Our New Dress; The Tehichepa Disaster, 49
Passing Events; Manufacture of Engines; Driver's Pat-
ent Mortising Machine, 56. Centering the Transit in
Mining Shafts, 57. Mines and Mining in 1882, 57-62.
Patents and Inventions; Notices of Recent Patents, 68.
ILLUSTRATIONS.—The Locke Patent Lead Smelting
Furnace, 49. Beckett's Improved Horizontal
Engine; Driver's Improved Mortising Machine, 56.
Improved Apparatus to Center the Transit by Screws
in Shaft, 57.
CORRESPONDENCE.—The Black Sand Question;
Notes from Eureka, Nevada, 50.
MECHANICAL PROGRESS.—Judging by the
Fracture: Iron Rust as a Cement; Shop Practice, 51.
SCIENTIFIC PROGRESS.—Practical Application
of the Lenscope; Bisulphide Carbon Lenses; Gum
Arabic in Certain Chemical Reactions; Poteline; Cheap-
ened Aluminum; A Curious Phenomenon; Soap Manu-
facture, 51.
MINING STOCK MARKET.—Sales at the San
Francisco Stock Board; Notices of Assemblages, Meet-
ings and Dividends, 52.
MINING SUMMARY.—From the various counties
of California, Nevada, Arizona, Colorado, Idaho, Mon-
tana, New Mexico, Oregon and Utah, 52-3.
USEFUL INFORMATION.—Luminous Paint;
Printing on Wood; American and English House-Build-
ing; Tempering Locomotive Springs; Sawdust Instead
of Hair; To Preserve Hickory Timber; Edge Tools;
Briekmaking without Baking, 55.
GOOD HEALTH.—A Marvel of Surgery; Face Ache;
Long Life; Value of Asses' Milk for Children, 55.
MISCELLANEOUS.—Wooden Water Pipe; Mining
Laws, 50. Substances Used in Amalgamating; Plum-
bago; Bad Mining Management; New Method of Separat-
ing Minerals; Some Reactions of Titanium, 54.
Tellurium in Copper, 55.

Passing Events.

During the past week we have had a suc-
cession of accidents, attendant with loss of life,
phenomenal as occurring in so short a space of
time. The dreadful accident on the Southern
Pacific railroad, where the train went rushing
down the grade, carrying with it to death a num-
ber of helpless passengers, was the first of these.
Then we read of the wreck of the *Cimbria* and
some 450 passengers drowned. Then came the
Giant Powder explosion at the works across the
bay, when a number of Chinese and one white
men were killed. All these accidents occurring
so soon after the fatal hotel fire in Milwaukee
have made nervous people apprehensive.

We publish this week a very complete and
full review of the mining interests in 1882,
giving figures of yield from the different sections,
and statistics and dates of value for future re-
ference.

Attention is also called to our new dress of
reading type, which much improves the appear-
ance of the PRESS.

A STORE at Gold Mountain, Nev., was robbed
on Thursday or Friday last by mounted and
masked men. The proprietor and two clerks
were killed. The road agents then proceeded
on their way to the store at Silver Peak, which
was also robbed by them, the proprietor and
one clerk being killed. Two of the robbers
were also killed.

Manufacture of Engines.

A new establishment for the manufacture of
vertical and horizontal engines and boilers has
been recently opened in this city at 44 First
street, of which F. G. Beckett is the proprietor.
Mr. Beckett has made the manufacture of steam
engines and boilers a specialty for many years, dur-
ing that time building upwards of 1,000. Mr.
Beckett has been on this coast some six or seven
years, but before that he had extensive works
at Hamilton, Ontario, where they built on an
average an engine a day. Thinking there was a

the bearings are made of extra length. The
valve rods work in substantial guides. The
balance wheels are of ample size and weight,
and are turned true for driving belt. The boil-
ers and engines are all tested and set to work
before leaving the works. Vertical engines alone
from 2 to 50 horse-power are made, and vertical
engines and boilers combined from two to 24
horse-power.

Mr. Beckett also makes a specialty of horizon-
tal engines of the type illustrated by the accom-
panying engraving. The engines are built in a
substantial manner on a massive solid box frame.

BECKETT'S IMPROVED HORIZONTAL ENGINE.

more extended field in this State than in Canada,
he came to this coast. He first spent a year or
two in the mines to obtain a knowledge of the
requirements of mining machinery, and has since
been employed in the large foundries in this
city.

He has just started the manufacture of hori-
zontal and vertical engines and boilers, claiming
for them beauty of design, neatness of work-

The cranks are turned and balanced. The
piston and valve rods, crosshead and crank
pins are made of the best machinery steel. The
crosshead is fitted with brass gibs, with a very
large area of wearing surface. The valve is a
plain slide valve having extra large wearing
surface at the bottom end, the valve rod being
carried in a substantial guide. The balance
wheels are turned and bored perfectly true,

the clutch is thrown in and the chain set in mo-
tion. At the same time the table where the
material to be mortised is placed is raised to
the cutter or chain so that the chain is only in
motion while doing the work.

There is also a chip breaker that holds the
stuff firm while it is being mortised and re-
leases it when the treadle is up. The chains
are kept tight with a screw and spring at the
top, and by loosening the screw the chain may
be easily taken off. The machine is provided
with all the standard sizes of cutters. The
table is so arranged that it may be set in any
desired position. The machine makes a clean
mortise, as it takes out the cores at the same
time, and the inventor claims that it will do at
least twice as much work as any other machine.
He states also that it will not split the most
delicate or cross-grained wood, and will go
through knots without breaking them out or
injuring the cutters.

This machine is specially adapted for mortis-
ing redwood doors such as are being made in
large quantities for South America and Mexico.
With the hub attachment it is excellent for
wagon work, as it will mortise hard wood with-
out boring.

The machine is of such capacity that it will
make a mortise as small as a quarter inch by a
half inch. Any length of mortise can be made
by moving the work and making several cuts.

The machine is made in a neat and substantial
manner, every part being fitted in the best way
and nothing but the best material used. The
cutter goes through the material with one cut,
so there is no need of turning it over. John
Driver, of San Leandro, is the inventor and man-
ufacturer of this mortising machine.

DRIVER'S IMPROVED MORTISING MACHINE.

manship, cheapness, durability and economy in
working. The vertical engines and boilers are
connected together on a substantial iron base
occupying little space, and may be easily
mounted upon wheels, rendering them well
adapted for agricultural purposes, or they can
be placed with perfect safety on a hoarded floor,
the insurance companies making no extra charge
for their use. They are very simple in their
construction, and can be run with safety by
persons of ordinary intelligence. The combined
engines and boilers (except the two and three
horse-powers), are all supplied with heaters.
The working parts, such as the piston rod, valve
rod, crosshead pin, etc., are made of steel, and

ready for the driving belt, and are of ample
weight for all purposes. The outboard bearing
is supplied with a separate sole plate, and the
engines are complete with governor ready to
connect to the boiler. Duplicates of all work-
ing parts kept on hand. This style of engine
is made from 10 to 90 horse-power. In addi-
tion to these specialties, Mr. Beckett is prepared
to manufacture engines for steam yachts and
launches, hoisting engines, donkey engines,
pumping and irrigating engines, etc.

The Western Union Telegraph Co., after long
consideration, has taken an important step in
the direction of putting all its wires in New
York under ground.

POWDER EXPLOSION.—An explosion occurred
at the Giant Powder Works, Fleming's Point,
Alameda county, on Sunday, by which 25 Chi-
namen and one white man met their death.
The cause of the explosion is not known, as all who
were in the house when the first one occurred
were killed. There were seven distinct explo-
sions, with a short time clapsing between each,
the explosions occurring in different isolated
buildings. The circumstances overthrow some
of the preconceived notions about this powder,
the separate explosions being contrary to gen-
eral theory. The large magazine, in which were
many tons of powder, remained intact.

MRS. THEODORE TILTON recently sought and
found employment as a nurse in a Brooklyn
sick room.

Centering the Transit in Mining Shafts.

The engravings on this page illustrate an improved apparatus for centering the transit in mining shafts by means of screws. The principle of the apparatus was described in the MINING AND SCIENTIFIC PRESS a few years ago; but the details have since been improved on by the inventor, Ernest Koch, of Sutro, Nevada.

By set screws *l* and *e*, and the iron bar *a*, the apparatus is well tightened against the roof and bottom of the drift, similar to the method adopted in machine drilling. The arm *g* will slide up and down on the bar *a*, and is well secured on the bar *a* by a ring *d* and a screw *c*.

The box *i*, on which the transit is screwed, slides on the arm *g*, being moved by a screw *n*, a sliding staff *k* guiding and steadying it. The transit can be turned around the bar *a* by the screw, and can be centered by means of the screws *m* and *u* under the plumb.

The light *q* may be slid up and down and turned on the bar *a*, a ring and screw *p*. Fig. 1 is a side view; fig. 2 a top view; fig. 3 is the apparatus as originally constructed.

The improvements in this apparatus are to facilitate the putting up of the transit as in timber or in rock, and particularly in inclines and shafts so it will be steady.

The apparatus is very useful in badly ventilated and hot mines. Before the connection of the Sutro Tunnel with the Comstock mines, when the tunnel was in over 1,000 ft., there was very hot and bad air, and Mr. Koch and his assistant fainted several times in surveying the tunnel line at the time Mr. Koch perfected the apparatus for centering the transit.

The correctness of the apparatus was perfect, and the inventor writes us when the tunnel connection was made and the air was pumped, the daylight of the tunnel entrance was seen a distance of 20,000 ft.

Mr. Koch has used his apparatus with success to survey with the leveling instrument during the excavation of the sub-drain to carry the hot water of the Comstock mines through the tunnel. A thousand miners were at work completing the sub-drain for the 2,000-ft. during 90 days, and Mr. Koch was compelled to survey the grade and not interfere with the working men. By the use of the apparatus it is very easy to change the height of the leveling instrument.

CONTINUITY OF DIVIDENDS.—Continuity of dividends for any lengthened period is not a characteristic of American mines. Dividend mines are not plentiful. The few that come under that head are oftener managed more with a view of making money out of the variation in the value of the stock, rather than out of the dividends. Hence the mine is worked to make big dividends for short periods, instead of small dividends for long periods. This is done by selecting ore of high grade for the mills, leaving the low grade to be worked to depress the stock and get it back. An honest management will not let a good body of ore become exhausted before prospecting for another, but will judiciously use the resources of the mine in its period of prosperity.

ASSESSMENT WORK AND PATENTS.—The Commissioner of the General Land Office says: L. J. Webster, San Francisco, Cal., Sir: I am in receipt of your letter of September 6, 1882, asking whether, after purchase money paid and Receiver's receipt issued, it will be necessary to continue annual expenditures until issuance of patent. In reply you are advised that no annual assessment work need be done after final entry is made.

SULPHUR MINES.—Superintendent Rhodes is actively working the Humboldt sulphur mine, Nev. They have a deposit of pure brimstone. All they have to do is to blast it out. Each blast sets the brimstone on fire, but they are

WARD.—The gratifying news comes from Ward that the outlook of that camp is very flattering. The Martin White mill started up about the 10th inst. There are 60 men employed in the mine and about 30 in the mill. Nearly

Mines and Mining in 1882.

A Review of the Work of the Year.

Since the year 1877, when the great Comstock bonanzas were yielding their millions, we have not had so productive a year from the mines of the United States as that of 1882. The total yield last year was \$92,411,835, which, compared with 1881, when it was \$84,504,417, shows a gain of nearly \$8,000,000. It must be remembered, also, that 1881 was the best year in 10 or 12, except the memorable years 1876 and 1877, when we were producing in the nineties. The main increase this year comes from Colorado, Idaho, Montana, Utah and New Mexico, in all of which regions many new mines have been opened.

Until a few years ago California and Nevada overshadowed all the other mining regions of the United States. Then, when the Comstock bonanzas were exhausted in Nevada and the Leadville discoveries in Colorado were developed, the latter State took the lead, California still being second and Nevada third.

One thing should be recollected in this connection that is often forgotten: What may be a big development in a new region might not be considered so in an old one. When a lot of men are prospecting a claim and good ore is struck in a new camp, the fact is heralded abroad as one of great importance, and considerable attention is paid to it as auguring success for the camp in the future. The inference is that most of the other mines near by are just as good. But when the end of the year comes and the results are figured up, perhaps some quiet old camp has far exceeded the yield of the new and "boomed" one.

For instance, a good many people imagine that California and Nevada are played out for mining, and that the mining industry is dead in both States. Yet at the end of every year these "played out" regions show a net product ahead of all the other States and Territories except one. They have remained second and third for some few years. The other Territories and States, much advertised and "boomed," with new mines, mills, reduction works, towns, railroads and all sorts of things, make a great deal more noise about what they are doing than do the old settled regions. California, for instance, this year yielded six millions more than any other State or Territory except Nevada and Colorado. She beat Nevada 1,000,000 and Arizona 7,000,000, and all the others run below her. And this in the face of a depression of her grand mining interests resulting from litigation, which other regions are free from.

Very little capital is coming to this State or Nevada, but a good deal is going elsewhere. The other regions will no doubt progress rapidly, and it is hoped they will. But then people should remember that there are other places which are at work at mines, and doing good work too, as results show.

A much broader region of mining ground has been prospected this year than ever before. Men have ranged over the mountains in every direction, starting new camps here and there and everywhere. Railroads are being extended in all directions, and the mining interests of the country being rapidly developed.

In New Mexico, Idaho, Montana and Arizona considerable prospecting is going on. Colorado, Nevada, California and Utah are now at work developing their old ones. Taken all together the work has been very satisfactory everywhere. More people are now interested in mining pursuits than ever before, and people are commencing to see that miners are not a set of stock gamblers. In fact, the operations at

IMPROVED APPARATUS TO CENTER THE TRANSIT BY SCREWS IN SHAFT.

prepared for this, and after a shot is fired they at once advance and throw water upon the burning mineral.

The Quicksilver mines at Steamboat Springs, Nev., sometimes called the Humbert mine, has been sold for \$2,013 to satisfy a judgment.

everybody has something to do, idle men being very scarce. The mill reduces from 50 to 55 tons per day. It has 20 stamps, and the ore is roasted. The ore goes on an average from \$120 to \$150 per ton.

The thermometer at Butte, Montana, recorded 61° below zero on Saturday.

The following tables show the percentage of gold and silver in the years named:

PERCENTAGE OF GOLD AND SILVER IN 1882

There is this to be remembered concerning the mines of California. The State is the oldest of what are known as the "mining States." The region has been longer settled. There are roads nearly everywhere, and many small towns, settlements and camps in every nook and corner of the mining region. Moreover, we are not confined strictly to mining, but may farm and mine too, or do both on the same land. The miners are not compelled to live in an unsettled, half-civilized region, but can live as much should in these days. Property rights are pretty well settled, titles are well founded and mines easy of access from commercial and manufacturing centers. Supplies are easily procured, the best of machinery readily procurable, and in most places the mines can be worked all the year round.

In addition to the quartz mines mentioned, nearly every interior county in the State has its quartz properties. Amador, Butte, Calaveras, Placer, El Dorado, Inyo, San Bernardino and others boast of their good mines, all of which we have more or less frequently mentioned during the year. The dividends for the year foot up \$1,449,900 against \$1,820,000 in 1881. This is only from incorporated companies. During the year 68 mines in 14 counties have leveled 121 assessments, aggregating \$1,547,467, as against \$2,237,550. A good many of the gravel claims have been embarrassed by litigation.

We have spoken at some length of the Bodie mines, Mono Co., and stated that the Nevada county mines, with those of that county, were the principal ones in the State. The following about Nevada county, from the *Foothill Tidings*, is to the point: No equal area in the world has produced more gold than has Nevada county, and no region known has the promise of an equal mining permanency. The gold is found in both quartz ledges and gravel beds. Nevada and Grass Valley townships are the principal portions in which quartz mining is carried on. Eureka and Washington townships, further east and higher of altitude than the two first named, have also many valuable quartz ledges. The mines in Grass Valley and Nevada townships have been systematically worked and developed for many years; those of Washington and Eureka have received but little of the proper kind of attention. The Meadow Lake mines are idle now. Rough and Ready township has many gold-bearing quartz ledges in its eastern portion, while in its west part are valuable deposits of copper. The great gold gravel region of the county is in the townships of Bridgeport, Bloomfield, Eureka, Little York and Washington. These are of immense extent, and of incalculable richness. These beds are worked by the hydraulic process for the most part, and enormous values of gold are annually washed out of them. There are some gravel mines in Nevada, Grass Valley and Rough and Ready townships, but they are not extensive—excepting at Moony Flat and Rough and Ready, where is the extension of the famous gravel leads of Tumbucto, Smartsville and Sucker Flat. The most famous of the present active quartz mines are the Idaho, New York Hill and Empire. These are dividend payers at the time of this writing. One of them, the Idaho, paid on the first Monday in December, 1882, its 162d dividend. The mine has produced over \$6,000,000, and has kept in constant employment and at three-dollars-a-day wages a large number of men. The Empire is the oldest of all the mines now working in this State, and it, as well as the Idaho, gives promise of indefinite continuance. The Allison ranch, North Star and some others that were celebrated as gold producers in times past will soon be worked again. Cheap water power for machinery will cause those mines to resume. A revival, or rather renewed impetus to mining is certain in the year 1883 in the rich regions round about Grass Valley and Nevada City.

All the other States and Territories are credited with their production of copper and lead, but California is not. She produces no lead, but does produce some copper. She produces, however, what no other region in the United States does, and that is, quicksilver. This year the State turned out over 50,000 flasks, each containing 76½ pounds of quicksilver, and worth on an average 35 cents a pound.

Iron.

During the past year more attention has been paid to the iron resources of California than ever before, and in iron manufacture particularly there is a very gratifying increase. The unfortunate fire at the Clipper Gap works of the California Iron and Steel Co. gave the infant iron industry a very severe setback, but the works are being rebuilt. It is expected that they will commence smelting about April 1st with a capacity of 50½ of the present consumption of the State. This is something which has long been looked forward to, and it is gratifying to note that the public spirited and progressive men who inaugurated these important works have every prospect of reaping an abundant reward, notwithstanding the misfortune experienced in the burning of these works. The iron made is of such a superior character that it meets a ready sale. When these works, with the Oregon and Puget Sound furnaces, are all in operation, this coast will produce a large proportion of the iron for its own use. As we have been long dependent on other markets for our iron, this change is a very gratifying one. The private circular of J. W. Harrison reviews at length the pig iron trade of San Francisco for the past year. Spot lots have rarely been as low as the price for loading, though there has been a steady decline in both throughout the year. About 80 per cent. of the iron melted here is known as Glengarnock, and this has declined from \$85 last January to \$28 in December. The Oswego furnaces in Oregon have passed into new hands, and the product hereafter will be converted into steel and used mainly in Oregon. The Oswego furnaces this year sent about 3,200 tons of pig iron to San Francisco, which realized an average of \$31 per ton. The imports here of all kinds for the past six years and the highest and lowest prices for Glengarnock in each year will be found annexed:

	Highest.	Lowest	Imports
1877, per ton	\$84.50	\$28.00	17,473
1878, " "	81.00	25.50	11,017
1879, " "	84.00	24.00	9,150
1880, " "	88.00	26.00	13,202
1881, " "	30.00	24.50	8,600
1882, " "	85.00	23.00	10,093

The average price for the six years is \$29.70 per ton, and the average imports have been 13,279 tons. The imports for the past year are the largest in the history of the trade. The consumption was also larger than in any previous year, amounting to 20,159 tons. The stock on hand at the close is 8,108 tons, and the quantity afloat 4,337 tons. The present stock is 5,000 tons less than the average for the past six years. There are strong indications that more iron will be melted in 1883 than in 1882. The Puget Sound furnaces will begin melting in a few weeks with increased capacity.

Quicksilver.

California is the only producer of quicksilver in the United States, the rest of the world's supply coming mainly from Spain. The quicksilver industry is somewhat depressed here just now, all of the mines not being at work. This is due to the metal being on the free list, and Congress has been petitioning to restore the duty. Two weeks since we had quite an extended article on the quicksilver industry in California, and need not now go over the ground again. The estimate of production of this metal in California this year is about 50,000 flasks of 76½ pounds each. The producing mines of the State, with their yield for 1882, as follows:

	Flasks.
New Almaden	25,807
New Idria	1,954
Redington	2,223
Sulphur Bank	5,133
Guadalupe	1,138
Great Western	5,279
Napa Con.	6,838
Great Eastern	2,127
Various mines	256

The figures given for the New Almaden are not authentic, the manager declining to make the product public; but the others are correct. Our exports this year were 34,770 flasks, and the following table will show our previous exports:

	Flasks.		Flasks.
In 1852.	900	In 1868.	44 606
In 1853	12 737	In 1869	24 415
In 1854	20 908	In 1870	13 788
In 1855	27 165	In 1871	15 205
In 1856	23 747	In 1872	13 080
In 1857	27 262	In 1873	6 350
In 1858	24 142	In 1874	6 770
In 1859	3 399	In 1875	29 909
In 1860	9 448	In 1876	41 140
In 1861	35 906	In 1877	40 280
In 1862	33 747	In 1878	34 280
In 1863	26 014	In 1879	52 180
In 1864	36 027	In 1880	31 648
In 1865	42 469	In 1881	35 260
In 1866	30 237	In 1882	34 770
In 1867	28 853		

The Commercial Herald says: Our production this year is 10,000 flasks less than for the year 1881, and nearly 30,000 less than in 1877, the year of the greatest production of this article. That of the Almaden mine, in Spain, for the year 1882 is not published as yet, but may be safely estimated the same, or more, as in the year 1881, 50,000, and this is understood to be all forwarded to the Rothschilds, in London. According to the London Board of Trade, returns for November, 1882, the receipts there for the first 11 months were 45,121 flasks; for the corresponding period in 1881, 47,573, and in 1880, 49,247, showing a slight decrease. To the quantity produced here and in Spain together, 100,000 flasks or more, should be added 10,000 to 12,000 furnished by the Idria mine, in Australia, making altogether as the world's production for the year, 10,000 to 15,000 flasks.

The question naturally arises, what becomes of this large stock, over 4,000 tons of metal?

Our monthly receipts at San Francisco are as follows:

Month.	1881.	1882.
	Flasks.	Flasks.
January	4,870	4,053
February	3,124	2,635
March	4,294	3,432
April	4,268	3,682
May	6,742	4,286
June	5,135	4,258
July	4,543	4,131
August	4,410	4,178
September	4,270	4,153
October	4,302	4,180
November	2,780	3,160
December	4,703	3,202

Totals	53,250	45,310
Shipped direct from mine to Eastern States & Nevada	6,385	5,510

Total production 58,635 50,820

Copper.

In a comparatively condensed review like this it is impossible to go into the question of copper product as freely as the importance of the subject warrants. There is a sort of copper "boom" just now, and many mines are being opened. We shall reserve for a future number a more full review of the subject. No furnace work has been done in this State, that branch of the business being still confined, as far as this coast is concerned, to Arizona, and in a limited manner to Nevada. The copper Queen, Clifton and Globe districts in Arizona are now producing at the rate of about 16,000,000 lbs. per annum of copper bullion, a great portion of which now seeks the Eastern market direct over the Southern roads. Copper cement production, says the *Commercial Herald*, is still limited to the Spencerville and Newton mines, and amounts to about 600 tons per annum, averaging 90 metallic copper; but works are now being erected by the Campo Seco Co. in Calaveras county with a capacity of 20 to 30 tons per month. The latter mining camp (Campo Seco) has come somewhat into notoriety during the past year by the re-opening of two old mines formerly worked in that district, viz: the Campo Seco mine by a corporate company, who are putting up reduction works as above stated, and the "Satellite," formerly the "Lancha Plana."

The production of this metal on the Pacific slope has been greatly increased this past year, until it has reached an output equal to 10,000 tons fine copper, as follows:

	Tons Fine Copper.
California area and cement (precipitate)	600
Nevada ores and bars	800
Arizona	8,600
Total	10,000

New mines have been discovered and worked, and numerous smelting furnaces have been erected all over the coast, especially in Arizona, while the old producers, as the "Copper Queen" and the "Longfellow" mines have increased their product considerably. The "Copper Queen" has turned out 4,200 tons bars, averaging 96½%; "Longfellow" about 2,000 tons, 92%; "Detroit" about 500 tons, and "Old Globe and Dominion" about 1,500 tons bars, about 95% fine. In California the principal producer is the "San Francisco Copper Mine," at Spencer-ville.

Coal.

San Francisco, from its geographical position, is an important coal market. California itself, while a comparatively insignificant coal producer, still does produce somewhere near 100,000 tons a year. But the coal fields of Puget Sound and British Columbia are near at hand, and the mines there are being gradually opened and developed, so that they now produce much more than formerly. Most of these mines are owned by San Francisco capitalists. A change within the past few years has taken place in the method of transportation of the coals to this port, steam colliers having taken the place of the old worn out barks which formerly did all the trade. This fleet of steam colliers is steadily increasing, and as it does our receipts of English coal fall off. We will always, however, receive large quantities of English coal by the vessels which come here in search of wheat cargo. According to the private circular of J. W. Harrison, the receipts for the past year were about \$46,000 tons as follows:

Coco Bay and Renton tons	39,100
Carbon Hill	54,400
Seattle	146,300
Mount Diablo	80,200
Eastern (Cumberland and Anthracite)	43,500
British Columbia	151,800
English and Welsh	138,575
Scotch	28,878
Australian	163,127
Total	845,880

There have been radical changes in the sources of supply as compared with 1881. The quantity from England shows a falling off of 92,400 tons, while from Australia, there has been a gain of 39,500 tons, and from British Columbia and Puget Sound a gain of 62,000 tons.

COLORADO.

The bullion product of Colorado for the past year shows a most marked increase over the product of 1881—having reached the large total of \$26,750,898 against \$22,000,000, the largest yield of any previous year. It may be of interest to our readers to note the gradual increase of the bullion product of this State since the discovery of the Leadville mines. For several years previous to 1877 the annual product had varied from six to eight millions of dollars. In 1877 the output was in round numbers \$7,000,000; in 1878 it was \$10,000,000; in 1879, \$15,

000,000; in 1880, \$22,000,000; in 1881, \$22,000,000; and in 1882, as already stated, it is about \$26,750,898. This is a very gratifying progression, especially in view of the fact that a large portion of the increase has been derived from new localities, where little beyond prospecting or "dead work" has as yet been done.

An Immense Mineral Field.

For many years mining in Colorado was principally confined to the central portion of the State, near to the locality of the original discoveries. Of late years prospectors have pushed out in all directions until every portion of the eastern slope of the Rocky mountains, from the very northern limits of the State to its southern boundary, is known to be rich in minerals of every kind. Not only gold and silver, but lead, copper, iron and coal are everywhere found. During the past three or four years prospectors have passed over the summit at several points, and almost invariably found the western slope quite as rich in minerals as the eastern. Much of the growing prosperity of Colorado is due to the energy and enterprise of her railroad men, who are constantly extending the facilities of transportation in every direction throughout the mountains. The railroad engineer trends closely on the heels of the prospector.

Improved Methods.

According to the *Tribune*, grades of ore are now being worked in Colorado at all the smelting and reduction works which could not be made to yield profitable margins two or three years ago. Scores of waste dumps, containing the accumulations of many years, have been assorted over, and thousands of tons gathered which gave the most gratifying returns. All this is the direct result of the introduction of methodical systems, and improvements added to every detail of the business, interjected or at least rendered possible by the extension of railways to nearly every principal mining camp. Take away these influences, restore the primitive methods and the expense incident thereto, and it would paralyze the whole industry. Ores which contain \$20 in silver per ton are now worked at a profit. Indeed, the greater part of the dividends paid are derived from this material. It forms the great wealth of the mines, for the high grades run in small seams and streaks, forming an insignificant feature of the whole mass of vein matter. Cheap transportation and the enlargement of facilities for reduction followed as a natural consequence of the period and its steam-carriage innovations. The concentration of power at a few points where open markets with active bidders contend for every ton of valuable ore produced, has wrought most salutary changes. If a mine is worth working at all it will yield material that can be marketed profitably if within easy reach of a railway.

The Leadville Mines

Are still increasing the aggregate of their yield. We give the following summary of the yield of this remarkable deposit since 1860:

1860 to 1870, gold from placers	\$0,400,000 00
1874, gold and silver	145,000 00
1875, gold and silver	113,000 00
1876, gold, silver and lead	85,000 00
1877, gold, silver and lead	555,330 00
1878, gold, silver and lead	3,152,025 00
1879, gold, silver and lead	10,333,749 00
1880, gold, silver and lead	11,187,097 00
1881, gold, silver and lead	13,170,576 00
1882, gold, silver and lead	10,393,255 00
Total	\$64,536,526 00

The San Juan Country.

Next to Leadville the greatest increase of yield is in what is known as the San Juan country, comprising the five southeastern counties of the State, and the locality where the most recent important discoveries have been made. These counties and the progress made in their development has recently been fully recorded in our Denver Exposition letters. The yield of this district for 1881 was reported at the paltry sum of \$40,000, while that of 1882 is \$675,000. This yield is mostly for ores shipped to distant furnaces, which could not be moved until the locomotive reached Silverton on the 4th of July last.

The recent discoveries on Red Mountain have contributed much high grade ore to the general yield of this district; but the principal cause of the increased showing is in the fact that when the road to market was opened many mines which had been under development for years without reward to the owners, because the value of their mineral was exhausted by charges for transportation and treatment, began to be operated in earnest, and with satisfactory results came new power for systematic enlargement.

A Grand Mining Country.

Taken as a whole, there is no mining region of equal extent in the world which can present so large and varied an exhibit of the precious metals in all their various combinations as Colorado, or so large an aggregate of yield. In the returns for 1882 no less than 19 counties figure in the list as producing the precious metals. These counties cover an area nearly if not quite equal to the entire mineral region of California, with an immense area of country on the western slope of the Rocky Mountain Divide on which the prospector has as yet scarcely set his foot.

In order to show the general diffusion of the minerals throughout the State we herewith append the

Bullion Product by Counties.

The bullion product of the State for 1882 was as follows:

Counties.	Amount.
Boulder.....	\$550,000
Chaffee.....	225,500
Custer.....	705,116
Clear Creek.....	2,001,629
Dolores.....	125,000
Fremont.....	19,960
Gila.....	2,006,516
Grand.....	10,000
Gunnison.....	600,000
Hinsdale.....	275,000
Lake.....	17,131,853
La Plata, San Juan.....	675,000
Ouray.....	329,760
Park.....	283,564
Pitkin.....	100,000
Rio Grande.....	310,000
Routt.....	100,000
Saguache.....	62,000
Summit.....	1,250,000
Total.....	\$29,750,898

Nearly all the counties which report a yield of \$125,000, or less, are those in which mining is just beginning to be developed, and yet, notwithstanding all that has already been done, the *Tribune* truly remarks that Colorado

Is Still in its Infancy.

In regard to the unrivaled industry of mining as a pursuit—only two shafts have penetrated the fissures to the depth of 1,300 ft., and not more than six or eight to the depth of 1,000 ft. The major part of our 26½ millions for this year came from mines less than 500 ft. from the surface. It must be understood also that all operators work for immediate gains. In other words, when a body of paying mineral is exposed by underground exploration it is stopped out for what it will yield, rather than left as reserve force for stock operations on the mining exchanges. The expense of a mine is in the amount of dead work required to expose reserves. A shaft determines nothing but the character and strength of the vein matter, yields nothing in comparison to its cost. It is in the stopes opened by levels where the profits are derived, because they contain values which can be measured and readily converted into coin. If all the fissure mines could be penetrated to the depth of 1,000 ft., and levels driven to the full extent of their ore chutes at intervals of 100 ft. before any stoping was done, a work requiring a large expenditure of capital without recompense, and from three to five years' time under the most favorable conditions, the output for the succeeding five years would be enormous. But mines cannot be worked in this manner. Consequently each owner or corporation conducts operations with an eye single to the benefits derivable from day to day. When the reserves are at hand he is happy in the possession of a plethora of bank account, and when exhausted he must needs hunt for more.

Future Stability.

In conclusion, continues the *Tribune*, we believe that unless serious injury shall be inflicted upon the mining industry by causes now operating against the price of lead and silver for a considerable period, this pursuit will be even more prosperous during 1883 than any former period. We are dependent to a greater degree than some are willing to admit upon the maintenance of the values of these metals which have prevailed for the past three or four years. The removal of the present tariff on lead or any material reduction would bring serious consequences, because we are producing more than one-half of the entire lead product of the United States. The demonetization of silver would close the mines and depopulate the districts.

Colorado Smelting Works.

There are three great smelting establishments in Colorado that are kept in constant blast to their fullest extent—the aggregate capacity of which has been nearly doubled during the past year. We give their products for 1882, so far as it has come to our knowledge, as follows:

Argo works.....	\$3,668,000
Pueblo works.....	3,272,405
Grant works (70 days).....	1,337,220
Two smelters at Golden.....	1,190,043
The La Plata, Arkansas Valley, Cummings and Fair.....	6,929,863
Total.....	\$15,404,531

There are many other smelting works scattered through various portions of the mines from which we have no returns. The Grant works are new and had run but 70 days up to Jan. 1, 1883. There are three smelters at Golden, but we have returns from only two. A considerable amount of ore from Utah and other localities is treated at the Argo works. The Pueblo works receive large amounts of ore from New Mexico and Arizona, the product of which appears in their total of returns. In the above total of furnace products there is no return from ores treated at the furnaces in Leadville.

Coal in Colorado.

The deposits of coal in Colorado are practically inexhaustible. They are found in nearly every section of the State, at and above the foothills of the Rocky mountains. The northern coal belt is a free-burning, semi-bituminous coal of air quality for heating and domestic purposes. This coal is sold in Denver city at from \$3 and upwards per ton. Most of the coal consumed in Denver is from this deposit. This coal is shipped east as far as Omaha. Arbitrary railroad rates prevent its going further. The product of this region the past year has been about \$550,000, which has brought an average of \$2.50 per ton at the mine.

The Middle Coal Region

Lies between the foothills west of Denver and the Colorado springs. This is also a fair domestic coal, and crops out at numerous points along the region designated, although but little has been as yet done in the way of its development.

The Southern Belt

Produces a superior article of coal, most of which is of a fine quality for coking. At Starkville, five miles from Trinidad, on the Atchison, Topeka & Santa Fe railroad, 100,000 tons were produced last year. Most of this coal was sent to the South and West. The value of this coal on cars at the mine is about \$2 per ton. At the same point 40 coke ovens are running, and these have produced about 225 tons of coke, worth \$4.50, which has been sent wholly into Arizona. They have not been able to fill all their orders for either coal or coke. The mines at Eagle will have shipped about 400,000 tons of coal, worth \$2 on cars at the mine at El Moro, and about 12,000 tons of coke, worth at El Moro \$4.50 per ton. Chappell & John's mine, south of Trinidad, has turned out 20,000 tons.

The Canyon Region.

The superior qualities of the Canyon coal are too well known to require notice in this hurried review. The belt includes the valley of the Arkansas, and is mainly, if not wholly, confined to Fremont county. The region is one of the oldest in the State, and the development is large, and the exhaustless character of the deposits have been proved. The output of this region for the year has been about 160,000 tons. The value at the mines is from \$2 to \$2.50 per ton.

The Gunnison Coal.

Gunnison county furnishes the most important coal-field in the State, whether in quantity or quality, the development of which is being rapidly made. This coal is both soft, or coking, and anthracite. During the past year 43,000 tons of soft coal have been raised and disposed of. Fully 10,000 tons of coke were produced in 1882 from this coal by one company—the Colorado Coal and Iron Co. The anthracite deposits have not as yet been largely worked, and only 2,000 tons have been marketed during the past year. There are five workable seams at one locality in Gunnison county—the Crested Butte—running from 3 to 15 ft. in thickness. Besides this locality there are hundreds of square miles of equally valuable soft coal in Gunnison county.

The anthracite of this county also covers an extensive territory, but it is not all of what may be considered a good quality. The anthracite interest of Colorado is just beginning to be developed. One of the companies, now actively at work, is putting up improved machinery—breakers and screens—with which it will soon be able to furnish from 200 to 300 tons per day. The coal belonging to this company is in all respects equal to the production of the best grades of steel, as has been fully proven at the Pueblo Iron and Steel Works.

Iron Products, Etc.

In addition to her other products, Colorado has also turned out during the past year from 53,000 tons of iron ore 24,000 tons of pig iron, which has been converted into 16,139 tons of steel rails, 3,883 tons of merchant iron and 2,752 tons of miscellaneous castings, 1,253 tons of muck bar, 16,155 kegs of nails and 5,022 kegs of spikes. With her immense resources of coal and iron ore Colorado promises in the near future to become one of the largest iron-producing States in the Union. The total railroad investment within the State reaches the enormous amount of over \$95,000,000 in value, the total length of the track being 1,397 miles, the gross receipts from which for the past year were \$9,135,544, which gave net earnings to the amount of \$3,654,816.

State School of Mines.

It is eminently proper that Colorado, which produces more of the precious metals than any other State or Territory, should have a State School of Mines, where a thorough education in chemistry and metallurgy, together with a practical knowledge of mineral geology and of the science of the reduction of ores may be obtained. This advantage Colorado now possesses.

The report of the operations of the school shows that the number of students in attendance is more than double that of two years ago, and that a large number of students who have graduated at Harvard University, the United States Naval Academy and other colleges of the highest standing are pursuing regular courses at this institution, which is good evidence that it is accomplishing well the purposes for which it is established. The large increase in the number of students compelled the management to either continue the school without sufficient room for any department of work or enlarge the building to meet the additional requirements. They determined upon making the addition, which is now nearly completed, and which will about double the building accommodations of the school.

NEVADA.

Nevada shows a falling off of \$1,484,188—the yield of the Comstock being \$1,333,018 as against \$1,726,162 in 1881, a decrease of \$393,144. Yet she still maintains her third place in the list of bullion producers, as she has since the Leadville mines of Colorado put that State at the head. Perhaps the situation in Nevada is best summarized by a quotation from the inaugural address of Governor Kinkadee delivered a few weeks since: "We have had no wild ex-

citements, as in previous years, over alleged vast mining discoveries, which have benefited the wary few at the expense of the credulous multitude. Stock gambling is not so prevalent as formerly. The mines have yielded fair returns in most localities, and in several the present bullion output is larger than ever heretofore. Legitimate mining is taking the place of stock speculation; new and prosperous mining districts are being organized, giving employment to many, and inviting the attention of capital to safe and profitable investment. The result must be beneficial to the State; its revenue will augment, and its population permanently increase. The growth of all other branches of business in our State depends, in great degree, upon extended and successful mining operations. Our neighboring States and Territories, through public spirit, private enterprise and fair railway charges, prompt inducements to investigation of their mineral resources, and offer reasonable guarantees for the safety and protection of capital from abroad to aid in the development of this important interest. I believe our State unequaled in the extent and variety of her mineral wealth. Much of this lies dormant for lack of capital and transportation facilities. The decline in the production of the great Comstock lode (which I trust will not be permanent) has, through unjust comparison, greatly retarded the prosecution of the mining industry in other portions of the State. In several districts remote from the Comstock mines are now being opened that give promise of a large bullion product in the near future. Improved machinery will utilize and render valuable our low grade and hitherto unproductive ores and ensure a more extended and profitable industry.

The product of Euroka district last year was \$3,176,700, a decrease of \$953,100 from 1881. This camp produced more than the Comstock last year.

The demands on Nevada last year were as follows:

Alexander.....	1	\$100,000
Bristol.....	1	14,000
Exchange.....	1	3,000
Eureka Con.....	4	75,000
Indian Queen.....	7	25,625
Nevada.....	4	15,000
Northern Belle.....	6	25,000
Richmond Con.....	3	270,000
Total.....	29	\$787,625
In 1881.....	56	1,397,500

As to the Comstock the *Enterprise* thus summarizes the situation:

In the California and Consolidated Virginia there is now open on the 2,700 and 2,500 levels about 1,300 feet of new ground—the California claim being 600 and the Consolidated Virginia 710 feet in width.

In the Best and Belcher mine there are 540 feet; Gould and Curry, 612; Savage, 771; Hale and Norcross, 400; Chollar, 700, and Potosi, 700, making in all, from the south line of the Potosi to the north end of the Sierra Nevada drift (2,700 level), a little over 8,000 feet of ground along the lode which, with but few and short breaks, is now open for exploration on levels ranging in depth from 2,500 to 2,900 feet.

In the opening out of these several deep levels by means of long main working and deep ventilating drifts, our leading mining companies have at last reached a point toward which they have been striving during the past four years. Just now, when the grand object has been attained, it is rather curious to see the stock of the several mines lower in price and apparently in public estimation than at any time since the commencement of operations looking to the opening out of these deep levels.

A year or two ago an impatient public in its mind's eye saw already completed the work not yet wholly finished, and began investing. No doubt almost every person who then invested thought he was putting in his money just in the "nick of time" and expected to see his pet stock go up the next day or the next week at the furthest. Those who thus invested have grown heart-sick at the long delay. Many have sold their stocks and many have had them sold by brokers. Some have doubtless held on through all discouragements (and assessments), but they have neither been in a condition or the humor to buy more stocks and thus assist in keeping up prices.

Now, when that is about to be done to which all have been looking forward, and when the proper time for investing has arrived, the masses are so much exhausted through their premature efforts, and so disgusted on account of their bad luck, that they look with suspicious eye upon Opportunity, though she turns toward them the handle of the jug. Had those who began the fight a year or two ago reserved their fire until the present time, their ammunition might have done gratifying execution.

Those who now put their money into stocks, whether or not they make fortunes, will have the satisfaction of knowing that they made their venture at the best time that could have been selected and at a price so low that any further decline would be impossible without the stocks going off the Board and out of sight entirely.

In Humboldt county the mining outlook is better than at any previous time for years. Rich ores have again been found in mines which have not been worked for two or three years. It is stated with certainty that work will be resumed on the Arizona mine, at Unionville, where large bodies of rich ore have been found while working the annual assessments. This mine will give employment directly and indirectly to many men and reinhabit the camp where it is situated. The Paradise mines are also looking better, and it is hoped that work will be resumed on the Paradise Valley and other pro-

ductive mines in the district before long. Willow Creek, a new and promising mining camp, is also coming to the front, and will be producing bullion within the present month. The Auburn and Lang Syne companies, at Dun Glen, are expected to resume operations on their mines ere long, and it is reasonably hoped that the season of greatest mining depression is at an end.

We have been giving every week descriptions of the mines in the various camps of the State, and have only room here for a few general remarks. As to the southern counties of Nevada, Mr. E. T. George, who lately visited them, says: During our trip through the southern part of Nevada we were surprised at the number of reduction works that had been erected in the different mining camps and lying idle, monuments of folly and mismanagement. If one-fourth of the amount of capital had been expended in exploring the mines that has been wasted in erecting those expensive works, our State would to-day be the greatest bullion producer in the world. Valuable mines are lying idle which, if worked on legitimate business principles, would be dividend payers, but useless expenditures and gross mismanagement have caused stockholders to refuse to contribute any further funds, and the mines and mills have become almost uninhabited, where heretofore all was life and bustle, and not on account of the merits or demerits of the mines, but simply for the incapacity and make-all-own-can-for-yourself management. Nevada has had "wild cat and stock jobbery" enough.

While our neighboring mineral States are enjoying a season of prosperity Nevada is undergoing a season of dullness unparalleled in her history, and through no fault of her mines or mineral wealth. We believe that our State is the best mineralized State or Territory in the Union, if properly worked, and in all our principal mining camps it has been proven beyond a doubt that our mineral veins are continued to as great a depth as in any other country in the world. Then why should so many of our mines be lying idle to-day? Let any person who has been a resident of those camps answer the question. Is it through the mines giving out, or on account of the poverty of the ore? Can they truthfully say yes in either case? There may be some few exceptions, but the greater number will have to be laid to the incapacity of the management and useless expenditures in salaries to non-producers. How many mines are there whose pay-rolls for miners and mill men equal the amount paid out to superintendents. Mining can be made a paying business, and will pay a larger rate of interest on the amount invested than almost any other business, but must be conducted on the same business principles that any other business is conducted on; then, and not till then, will our State return to its old prosperity, and it should be the endeavor of all interested in mining and the welfare of the State of Nevada, to do all in their power to encourage legitimate mining and discourage wildcat schemes and stock jobbery.

The Carson and Colorado railroad will open up all the districts in southwestern Nevada and help the State out wonderfully. The region traversed by this road abounds in mineral, but the camps have languished owing to lack of transportation facilities. With this new road running, however, these difficulties will be overcome. The copper resources of the region alone would be sufficient to make a prosperous one, but there are many other minerals as well. There is little doubt that Nevada will again resume her vigor when the present temporary depression wears away. She is doing now a great deal more bullion producing than many of the more advertised States and Territories, standing, as we have said, third on the list.

ARIZONA.

As will be seen by Wells, Fargo & Co's estimate of bullion product, Arizona yielded in 1882 \$9,298,207. The estimates made in Arizona considerably exceed the amount. The following table prepared for the Tucson *Star's* annual edition shows a different result:

The gold and silver output of Tombstone takes the first rank, after which comes the copper output of the Territory, and third, the gold and silver reported from the Territory at large, and lastly, estimated output not reported, the whole footing up \$11,702,294.28.

Tabulated Statement.

Silver King, silver bullion.....	\$375,000 00
Silver King, concentrations.....	400,000 00
Tip Top, silver.....	243,081 00

Copper Output.

	Pounds.
Copper Queen Co., operating the Copper Queen mine, in Cochise county, Warren district.....	8,045,320
Arizona Copper Mining Co., operating the Longfellow and Coronado mines in Graham county, Clifton district.....	4,325,000

Old Dominion Copper Mining Co., operating the Old Gila and Dominion mines, Gila county, Arizona	1,940,000
Buffalo M. and S. Co., operating in Globe district, Arizona	431,400
Pima County Copper Mining Co., operating in Pima county, Silver Bell district, Arizona	961,500
Columbia Copper Mining Co., operating the Bulldozer and other mines in Pima county, Santa Rita district, Arizona	418,000
Russell Gold, Silver and Copper Mining Co., operating the Peabody mine, in Cochise county, Dragoon district, Arizona	264,656
Delmont, operating in Clifton district (estimated)	250,000
Long Island Copper Co., operating in Gila county, Globe district, Arizona	453,680
Total value of copper	\$2,915,354.40
Total of Tombstone	\$5,302,876.35
Value of outside districts	2,634,133.53
Value of copper bullion	2,945,254.40
Estimated output not reported	1,500,000.00
Grand total	\$11,702,234.28

These figures show the product of the principal camps, but many small mines not mentioned are at work. A great deal of prospecting is now being done in Arizona, and within a year many more mines will be developed. One difficulty now is that where there are a number of prospects partly opened the men have not money enough to go on with the work.

It will be noticed that the copper output of the Territory is now very large. It is, moreover, increasing, and will no doubt be doubled before very long.

Our space will not warrant mention of all the mines in the Territory, or even the districts. We have during the past year paid a great deal of attention to the mines of Arizona, and given, from week to week, all the general news. We now, therefore, only sum up the results.

The principal camp, Tombstone, has not done what was expected of it. There were several reasons why the yield did not yield \$5,000,000. First came litigation, closing down three mines for the greater part of the year, and second, the closing down of one of the Tombstone Mill and Mining Co.'s mills the 1st of May, which reduced that company's output by about \$1,000,000. To partially make up for the deficit, the Stonewall mine, which was purchased by the Boston and Arizona Smelting and Reduction Co., was opened out and became quite a large producer, and several other claims were put upon a paying basis in a small way. The total output was \$5,302,876.35. If the Head Center-Tranquility starts up within any reasonable season, it should add at least \$1,000,000 to the present year's product, and then Way Up, Ingersoll, Luck Sure, Little Devil, Blue Jacket and Contact will come in to swell the amount, so that this year's yield ought to approximate \$7,000,000.

There are many prosperous camps in the Territory of which very little is said. Of most of these we have published notes from time to time. The smaller mines, which furnish no figures of bullion product, but which yield more or less each year, are those which keep a large population of miners at work and in which the miners themselves are generally interested. Of this large class it is impossible within the limits of a review like this to say very much. Arizona promises to increase her yield of bullion annually for many years to come.

NEW MEXICO.

New Mexico rolls up \$3,067,132 as her bullion product this year, a very respectable showing, placing her number seven on the list of bullion producers. Last year the Territory produced \$814,244, and the year before that only \$711,300. The increase of 1882 was therefore very marked and quite satisfactory. The region labors under the difficulty of being new as a mining field. That is, it is only of late that it has attracted much attention from capital. Even now capital has come in more slowly than should be, and there are many properties waiting buyers. It is stated, however, that the development is retarded by reason of so many persons holding ground and only doing assessment work on it. The Commissioner of Immigration of New Mexico, Chas. W. Greene, says, in speaking of mining in 1882: Looking back over the year just closed we find a marked progress in development of the mining industry of this Territory. At the beginning of the year almost everything that could be said of it was of its prosperity in the distant past, or of its hope for the future under the new regime just inaugurated. The practical questions were often asked: "Where is the product of the mines, for which so much is promised?" "Why no output from the large number of mines you tell us about?" Save the operations at Georgetown, Santa Rita and Silver City, and for a brief period at Socorro, there was no real mine production, and but little practical mining. Smelters were talked about, and mills in several parts of the Territory. One had been built and was standing idle at Cerrillos; another, the Duray, had proved a failure at Bonanza City; another had been built and was making spasmodic efforts to obtain ore at Socorro; another novel electric process was about being tried at White Oaks; a small mill had been built at the same place, but had not been successfully operated. Prospects by thousands had been located and recorded; upon some of them two or three assessments had been worked; on much the larger proportion only one assessment, if any, had been worked. Mines, in the full sense of the word, were very few and far between.

To one who has watched the changes of the year, there has been much to encourage and but little to disappoint. The advance has been steady; there have been but few failures, and where either labor or capital has been employed it has generally yielded gratifying results.

There is no accessible record, and necessarily the observation of any one person covering the whole field must be somewhat cursory and imperfect. There is enough, however, at command to make good the assertion that more has been accomplished within the one year than in all the preceding time since the industry was newly established.

UTAH.

Utah Territory is one of those which shows a gain in bullion production this year. The mineral yield is the highest experienced. The mines seem to be in a prosperous condition, and to be advancing to development in an exceedingly satisfactory manner. The Salt Lake Tribune is sued on the 1st inst. an edition in which were very elaborate special articles, describing in detail the work of all the mines in the various districts. This made a voluminous review of the mining industry of Utah very creditable in every way. We are unable, of course, to go into details about the 80 mining camps of the Territory, but collate from the Tribune an abstract which shows general results.

The totals of values of bullion produced are as follows:

Value of product of 1882	\$5,143,175
Value of product of 1881	7,353,658

Excess of 1882..... \$789,517

The most of the increase must be credited to lead and copper, the product of silver being as follows:

Ounces in 1882.....	5,435,441
Ounces in 1881.....	5,406,191

Being but a trifling gain. But the gain of this year is a Utah gain, which could not quite have been said of the gain of 1881 over the year before.

In 1881 there were received from Idaho, Montana and Nevada nearly 2,000 tons of lead, 441,846 ounces silver and 976 ounces of gold, all of which went to swell the bullion statement for Utah of that year. But for 1882 the amount of ore received from points outside this Territory has been so insignificant that it wasn't worth while to state it. The statement, therefore, is an unusually gratifying one, not only as to the large aggregate produced, but also from the fact that it shows an increase for Utah mines much greater than the simple comparison of the aggregates would indicate. Thus, the product in lead shown in the general statement is, in pounds:

For 1882.....	52,849,850
For 1881.....	42,101,625

Increase..... 10,748,225

But to get the actual increase of Utah production, the 3,969,440 received in 1881 from outside the Territory must be added to the balance shown, making the increase for Utah 14,127,665 lbs.

In like manner, the general aggregate shows an increase of but 35,253 ounces in silver; but if from the product of 1881 we deduct the 441,846 ounces received from our neighbors in 1881, to balance which there were no receipts from the outside for 1882, we perceive the real increase in Utah's silver output to be 477,099 ounces, or a handsome margin over half a million dollars. The above values are given on a basis of Utah value; about 25% must be added for the sea-coast value. The general situation, then, is one of great prosperity and satisfactory growth.

The Smelters.

The great smelters not working in connection with any mine or mining company are the Germania, the Hanauer and the Mingo.

The Germania shows a production the past year of 8,213,789 lbs. of refined lead, against 2,645,373 lbs. the year before; 561,777 lbs. unrefined lead, against 3,687,284 for 1881; 388,614 ounces silver, against 349,479 the year before, and 815 ounces gold, against 508 ozs. in 1881. This shows an enormous gain in lead production, especially refined lead; and a handsome gain in silver and gold.

The Hanauer smelter produced 5,602,324 lbs. unrefined lead, against 3,015,228 lbs. in 1881; 254,339 ounces silver and 1,384 ounces gold, against 176,320 ounces silver and 438 ounces gold the year before.

The Mingo furnace produced 10,128,738 lbs. unrefined lead in 1882, against 11,977,649 lbs. in 1881; 316,309 ounces silver against 437,176 ounces the year before; and 816 ounces gold against 832 ounces.

Park City.

For many years Park City has been the leading mining district in Utah, and the Ontario has been its mainstay and life. The Ontario is one of the few great mines of the world. It has a record of steady dividends and never an assessment. It has produced an aggregate of \$12,295,265.92 in silver, and has paid \$6,150,000 monthly dividends, amounting to \$5,150,000. For the year just closed its product has been 1,522,664 ounces of silver, compared with 1,909,870 ounces in 1881. The product of the company is only gauged by the capacity of the mill to reduce the ore. This milling capacity is to be doubled next summer by the erection of a new mill of equal capacity with the present one. The value of the Ontario product at the standard adopted by Wells & Fargo (\$1.123 per ounce) amounted to \$2,084,246.90. From this have come 12 regular monthly dividends of \$150,000 each or \$900,000.

Another company which, by the recent settlement of conflicting claims and titles, has become a fine producer is the Crescent, shipping both ore and bullion. Its product, however, is not stated separately.

Other properties in Park City and vicinity are fully treated of in the special article in this issue devoted to that camp.

Frisco District.

The great Horn Silver mine is in this district; it has much the largest mass of ore in sight of any mine now being worked anywhere. Within the year just closed the company which owns this mine has overhauled and passed its great Utah rival, the Ontario. The product of the Horn Silver for 1882 was 1,620,357 ounces silver, and 32,003,775 lbs. lead, against 1,259,903 ounces silver and 16,343,995 lbs. lead in 1881. Value of silver, 1882, \$1,882,901.62; value of lead, at \$52 per ton, \$832,052; aggregate value of product, \$2,654,953.62. But this is the Utah valuation; at the seaboard the company actually received for its product considerably more. It received \$2,521,687.68 for 1,255,111.32 ounces of silver and 11,803 tons of lead sold up to September 30th, 1882, the sum of \$2,521,687.68. At the same ratio, its added product since would bring the total of sales up to \$3,311,686.80. From this there have been paid four regular quarterly dividends of \$300,000 each, aggregating \$1,200,000, and another dividend of the same amount is due February 15th, and will doubtless be paid promptly.

The Frisco Mining and Smelting Company's product for the year was just about the same as last year, being 3,027,424 lbs. lead and 214,320 ounces silver. But in gold it made a jump from 425 ounces in 1881 to 882 ounces in 1882.

Silver Reef.

The product of Silver Reef is steady, being 621,879 ounces for the year just closed, against 614,368 ounces, for the year before. The camp is holding out well in permanence, and will from all appearances be a regular producer to the extent of nearly three-quarters of a million dollars annually.

Tintic District.

The independent producers of this district are the Mammoth and the Tintic Mining and Milling Co. To the former is to be credited the matte reported in Wells, Fargo & Co.'s tables, 605,880 lbs., with 67,320 ounces silver and 1,683 ounces gold; a clear increase, nothing being reported from there in 1881.

The Tintic Mining and Milling Co. produced 59,814 ounces silver and 417 gold, a total value of \$76,230.75, to which the usual addition is to be made in reckoning the difference between values here and at the seaboard.

Other Districts.

The other districts, Bingham, Little Cottonwood, Big Cottonwood, Marysvalle, American Fork, Stockton, etc., are not separately stated, their product going in to swell the aggregate production of the smelters.

The following tables show Wells, Fargo & Co.'s statement of the mineral product of Utah for the year 1882:

BASE BULLION.	Pounds Lead Refined.	Pounds Lead Unrefined.	Ounces Silver.	Ounces Gold.
Frisco M & S Co.	3,027,424		214,320	882
Germania Lead Works	8,213,789	561,777	85,082	169
Hanauer	5,002,324	254,339	1,384	
Horn Silver M Co.	32,003,775	1,620,357		
Mingo Furnace Co.	10,128,738	316,309	816	
Other Smelters	966,600	58,606	13	
Total	8,213,789	64,200,98	2,648,073	3,264
Deduct base bullion purchased by Germania Lead Co.	713,885		44,968	124
Net product base bullion	8,213,789	51,576,668	2,490,005	3,140
Lead, silver and gold in ores shipped		773,197	15,464	193
Matte containing copper, 605,880 lbs.			67,320	1,683
Total, 605,880 lbs.	8,213,789	52,349,860	2,581,769	5,016
DORE BARS.				
Germania Lead Works			308,532	646
Ontario Silver Mining Co.			1,853,064	
Silver Reef District			921,879	
Tintic M & Co.			59,814	447
Other Mills and Placers			15,766	2,930
Total Dore Bars			2,853,665	4,022

RECAPITULATION.		
605,880 lbs. copper, at 12 1/2 cents per lb.	\$ 75,735	
8,213,789 lbs. refined lead, at 5 cents per lb.	410,690	
52,349,860 lbs. unrefined lead, at \$52 per ton.	1,361,096	
5,435,441 ozs. silver, at \$1.123 per oz.	6,114,874	
0.089 ozs. gold, at \$20 per oz.	180,750	
Total export value	\$8,148,175	

Computing the gold and silver at its mint valuation, and other metals at their value at the seaboard, it would increase the value of the product to \$10,312,902.

The following is a comparative statement showing the quantity of the silver and gold contained in base bullion produced in Utah:

Year.	Total ounces of gold produced.	Total ounces of silver produced.	Value of gold in base bullion.	Value of silver in base bullion.	Percent of total gold product.
1877	4,350,703	17,325	2,102,095	11,035.48	2-10 63-60
1878	4,357,328	15,040	2,103,339	10,165.48	3-10 67-61
1879	3,835,407	15,932	1,797,589	5,693.46	3-10 35-70
1880	3,783,666	8,621	1,403,810	2,475.37	1-10 35-80
1881	5,400,191	7,958	2,648,899	2,624.48	9-10 32-90
1882	5,435,441	9,080	2,581,769	5,016.47	3-10 55-60
Total	17,171,279	73,314	12,037,583	87,409.46	5-10 51-210

The following shows the quality of Utah's bullion:

Year.	Total value of precious metals, including gold and silver contained in base bullion.	Total value of gold bullion, including gold and silver contained in base bullion.	Percent of gold product.
1878	\$81,151,622	\$14,710,581	18-1-10
1879	76,349,561	19,254,394	25-6-10
1880	80,167,830	28,114,504	35
1881	84,664,417	30,253,430	36-8-10
Total	\$321,176,456	\$92,342,909	28-7-10

IDAHO.

Idaho Territory this year shows a total production of \$3,325,738, against \$2,334,474 in 1881. This is quite a gain, but not so much as was expected from the number of new mines opened and the new reclamation works started up. The only two incorporated mines which have levied assessments were the Pilgrim, \$14,000, and the Western Home, \$5,000. The Castle Creek Gold Mining Co., of Idaho, paid its first dividend of 3 cents per share, or \$3,000, last June. It paid the same amount in July, August and September, making four dividends this year, or \$12,000. Holyoke paid its first dividend of 2 cents per share, or \$4,000, in October. In November it paid 3 cents per share, or \$6,000, and in December 2 cents per share, or \$4,000. The Custer and Gold Hill have done well this year. Of course there are many other mines which have been profitable to their owners of which no public mention has been made.

The smelter at Challis, with one stack, shipped 38 carloads of bullion. The owners, the Omaha Smelting Co., also shipped five carloads of ore so rich that it was nearly equal to bullion. Besides they have shipped one carload of copper matte, and have stock on hand left over of a few thousand dollars in value, making a grand aggregate for the year, together with the light stock on hand, of \$425,000. This, for one inexpensive plant, is a little hard to beat.

In Warm Springs district (Ketchum) the operations of the season, according to the *Krysnoe*, resulted in general satisfaction both as to outputs and developments. Results in general have been very gratifying, and the future looms up fat and hopefully encouraging. The season started in late, but when once going the mills were alive with enterprise and activity, owners were developing, and prospectors were in search of the precious metals. Thousands of tons of ore were turned out and hundreds of new locations made. The records of the district show about 300 of the latter, and the Philadelphia Mining and Smelting Co.'s records show the following among other interesting facts:

Ores purchased	Pounds
Philadelphia Co.'s ores received	2,839,437
Total	4,269,350

This has not all been reduced, a good supply for a spring start being on hand, but sufficient was reduced to turn out nearly 2,000,000 lbs. of bullion of an average value of 250 ozs. silver per ton. The mines from which most of this ore was received, with amounts and average value silver, are as follows:

	Pounds.	Ozs. per ton silver.
Elkhorn	1,950,000	70
Erwin	600,000	60
Blackhawk	200,000	90
W. Fork	140,000	105
Black Horse	75,000	80
Isabella	65,000	105
Mountain Girl	21,000	65
Ontario Queen	13,000	75
Carle Leonard	8,500	100
Moonlight	7,400	265
Occidental	7,000	65
Back Bay	4,500	212
Paymaster	6,000	35

There are 56 mines from which shipments have been made to this smelter, a few of them in neighboring districts, but nearly all in our own. The Ontario shipped \$20,000 worth to one place out of the district, while many other mines have fine lots of ore on their dumps ready for sale or shipment, when markets and transportation facilities are more favorable, as they certainly will be.

Little Wood River mining district, which figures so prominently among the producing mineral sections, is situated near the center of Alturas county, and embraces an area of about twenty-five square miles. Little Wood runs parallel with Big Wood river, and is about twenty-five miles east of the latter stream. Muldoon, the town and supply depot, is situated near the head waters of the river, and twenty-five north of the crossing of the Blackfoot road, with which it is connected by a good wagon road. Shoshone, the junction of Wood river and the Oregon Short Line railroad, is distant about fifty miles, also approached by good wagon road. The great Muldoon group is the best developed among the mines. The owners of the Muldoon group mines also own and operate very fine smelting and sampling works under the title of Little Wood River Mining & Smelting Co. The works are three miles from the Muldoon mine. These works consist of a plant of two 40-ton smelting furnaces, with all the accompanying machinery, such as crushers, sampling works, etc., all of which are propelled by a 100-horse power steam engine. There are about 100 tons of bullion piled up at the smelter now. Among the mines near by are the Mountain Boy, Josephine, Jones & Davis, Gen. Garfield, Bonanza Boy, Buckhorn, Rose Abby, Iron Clad, James, Rippetto, Narrow Gauge, Hoodlum, Karriek group, Good Hope, Monitor, Lexington, etc.

The Yankee Fork region seems to have been prosperous this season. Although the camp has been in existence as a placer mining region of some note for seven or eight years, it is only since the purchase of the great Custer mine that it has been known to the general public as a large bullion-producing district, and just as its fame in that line began to spread, Wood River country loomed up, and in a measure overshadowed it. Placer mining on Jordan creek began in 1874-5, and had been in progress at and near the mouth of Yankee Fork of Salmon river for some years prior thereto; also at Loom creek, 18 miles north. The Charles Dickens mine is the "boss" lode of the region. The Dickens lode is now known as a great and continuous or mother vein, extensions having been discovered and located continuously for miles, among the more prominent of which are the Pilot, Paradise, Passover and George Washington. There are 6,000 tons of ore run on the Charles Dickens dumps.

One and a half miles north of the Dickens and across the canyon is the great Custer, which lies in direct line with the Dickens, and is undoubtedly a continuation thereof, the ore being similar in character. The Custer has a brief history, its fame as yet only maturing; discovered in 1878; traded for a butcher shop; almost abandoned; gradually attracting attention; then in the courts, and finally sold for about \$100,000 in 1879. A 20-stamp mill built in 1880 commenced operations in the spring of 1881, and the returns thereof in bricks of gold and silver bullion to date foot up in value to a most enormous sum of \$2,000,000, and that all from surface ore, the mine as yet being undeveloped underground; ten additional stamps are now being put into the mill.

The Salmon River mines include the great districts of Bay Horse, Poverty Flat, Squaw Creek, etc.

The Squaw creek mines are principally owned by J. D. Murphy & Co., a New York City firm, Capt. C. B. Rustin and Messrs. Conover & Gaunt. But little has been done the past season on any of the locations.

Situated near the head of East fork of the Salmon river are what is known as the Germania, Arctic, Idaho, Bible Back, Washington, Croesus, Tyrolense, etc. The Germania shipped from July 1st to Nov. 1st 86,000 lbs. of ore that averaged 180 ozs. per ton.

The mines in Yellow Jacket district, situated about 40 miles north of Challis, are principally gold producing, and report speaks favorably of them. The principal mine in this camp has been owned and worked by Dr. Van Horn, and has just been sold to San Francisco parties for the sum of \$30,000. The Bay Horse Mining & Smelting Co.'s smelter, situated on Bay Horse creek, has a capacity of about 20 tons. On the 15th of last June this furnace commenced work in earnest, and the result to the first of December, when the works were closed, there was 40 tons of bullion, valued at \$850 per ton or \$34,000.

The Salmon River Mining & Smelting Co.'s smelter, situated on the banks of the Salmon river, at Clayton, has a capacity of about 30 tons, but only run 20 days the past season. The bullion produced was of a good grade.

Blackhorn district is a new and important region just opening up, the great Tyndall lode being the chief.

Leesburg district in northern Idaho is fast becoming known as a region of great possibilities.

Sawtooth district is on the extreme northerly tributaries of the Shoshone Salmon, and separated from the Wood River country by a range of mountains, over which is a good wagon road. The distance from Vienna and Sawtooth to Galena, head of Wood river, is 15 miles; to Ketchum 40 miles; to Hailey 55 miles; to Bellevue 60 miles. The mines of Sawtooth district are divided into a number of belts. Those near Vienna are known as the Smiley Basin mines, and those in the vicinity of Sawtooth (seven miles north of Vienna) as the Beaver Canyon and Salt Creek belts.

Next year will make a very great difference with Idaho. There has been a great deal of preliminary work done in the Territory this year. New reduction works have been put up, new mines opened, and old ones put in shape for development. Capital has been attracted to the newer regions—and even the old ones, like Owyhee, Boise, etc., have experienced a revival. Next season Idaho ought to be ready to turn out a great deal of bullion. It has suffered badly from lack of means of transportation, but these will before long be supplied, and the mines can then be better worked. There is yet a great extent of unprospected territory in Idaho.

MONTANA.

Montana is credited last year with the production of \$8,004,000, while she produced only \$4,359,071 in 1881, and \$3,822,379 in 1880. Her progress is steady and rapid. The biggest camp in Montana is Butte, and she produced the most bullion. The *Inter-Mountain* of that place says:

A careful review of the mining, milling and smelting affairs of this camp can lead but to one conclusion, viz.: that the outlook for the mining interest of the Summit Valley district for the season of '83 is fully as high as the most sanguine friends of the camp expected, and far brighter than that of any other camp on the Pacific coast. Owing to the depression in Eastern mining circles, and to the fact that so many speculators in Colorado properties were outrageously swindled by the methods in vogue in that State, no little distrust as to the legitimacy of mining as a business has been infused into the

public mind, and really meritorious camps, great and permanent producers like Butte, have been condemned as being unworthy of confidence as the veriest wild-cat, knife-blade district in the country. Thus it is that the city of Butte has not this fall enjoyed the bustle and excitement of a big boom, which, in the minds of some mistaken persons, is the only evidence that a camp has rich and productive mines. That the boom did not strike Butte is extremely fortunate, but if anyone thinks that because this district is not now the scene of extravagant flush times and crazy mining speculation the mines have shown the slightest deterioration, never was he more grievously in error. The fact is, that Butte to-day is shipping more bullion and matte than ever before. The mines are being worked to the deep, and solely on their merits. The ore in sight at present is twice as great in amount and fully as rich as one year ago. Our silver properties show constant improvement, and the copper mines have developed truly wonderful productive capacity since December, 1881, when the copper interest was looked upon as comparatively unimportant.

The Aliee, Lexington, Moulton, Silver Bow all have the latest improved hoisting machinery in operation, most of it having a power capable of sinking to the depth of 1,000 feet. The aggregate number of stamps represented is 210. But productive and lasting as the silver mines undoubtedly are, they are likely to find formidable rivals in the copper properties now being opened up. The Colusa for the past two years has produced from 50 to 100 tons of ore per diem, much of which has been shipped in a crude state, the remainder being smelted in the magnificent works which are now turning out on an average 18 tons of copper matte each day. The Parrot company is putting up new and heavy machinery, and expect to tax its power to the utmost in hoisting the immense quantities of ore now available for extraction in the Parrot mine. The 50-ton smelter is easily kept supplied. A competent authority states that the Parrot could now produce 150 tons per diem of first-class ore if desirable. The Ramsdell Parrot and Shakespeare Parrot are also heavy producers, either of which could supply a 50-ton smelter with plenty of work. The Boston and Montana Company are working four mines, and the smelter is turning out copper matte at the rate of \$1,000,000 per annum.

In the Butte *Inter-Mountain* of the 13th we find the following: Owing to the fact that some of our mining and milling companies have not before completed a statement of their work for the year just closed, it has been impossible for the *Inter-Mountain* to present to its readers a correct and authorized tabulated statement of the year's production of silver, copper and gold in this district. Even now it is impossible to collect all the statistical details of the product, but the following figures, as far as completed, are correct:

Aliee Co. assay.....	\$ 850,000
Moulton Company.....	406,92
Silver Bow Company.....	48,473
Lexington Company—this month run.....	340,100
Dexter Mill—Anaconda Company.....	100, 00
Colorado and Montana Company.....	865,000
Montana Copper Company—matte.....	1,4 8,000
Montana Copper Company—ore.....	12, 40
Bel Company—January to June.....	324 00
Parrot Company.....	1,75,000
Longmead Concentrator.....	12, 000
Total.....	\$6,831,793

These figures are somewhat startling, but they are nevertheless true, and within a few days such additions will be made to the table by statistics not now obtainable of crude ore shipments, that the grand total will be swelled to \$7,000,000.

The following table, showing the value of gold and silver bullion deposited at the United States Assay Office at Helena during the year 1882, is published by the *Helena Herald*. In the item of gold deposited and treated the amount has increased yearly since 1877, the present annual showing being nearly double of that six years ago, and exceeding that of 1881 by upwards of \$100,000. The slight falling off in the silver deposits is owing to the increase of shipments direct from contiguous mines to the East, being a saving to the companies in the item of freights. The bulk of silver bullion produced in the Helena district is transported to market in its crude form, and of course does not appear in the assay office figures:

Months.....	Gold.....	Silver.....
January.....	\$32,669.93	\$ 4,063.07
February.....	60,622.81	12,665.95
March.....	21,984.63	14,194.12
April.....	53,523.69	15,765.50
May.....	50,701.94	12,222.20
June.....	72,723.69	15,532.93
July.....	80,173.89	3,597.97
August.....	62,676.58	1,414.79
September.....	73,594.31	1,700.97
October.....	73,453.54	2,772.12
November.....	61,394.32	1,830.54
Dec., estimated.....	16,000.00	4,000.00
Total 1882.....	\$678,925.33	\$91,013.16
Total 1881.....	\$70,536.63	\$8,714.04
Increase.....	\$108,388.70	\$7,700.88

TEXAS.

This is the first year that Texas was ever mentioned in the bullion tables, and it is credited with a yield of \$257,597 in silver. The most abundant metallic product of the State is copper. The copper belt extends from the Red river and the counties of Clay, Archer, Wichita, Haskell, etc., across the Rio Grande, through the counties of Pecos and Presidio, and yields, in immense quantities, an ore which will smelt on an average 55% of pure copper. In the immediate vicinity are found timber and fluxes, Argenteiferous galena is found in northwestern Texas. Manganese, cobalt, nickel and bismuth are also found. Iron occurs in the same region as copper. There are also large coal fields.

OREGON.

We have from week to week given the current news from the Oregon mines, but, compared with the work done elsewhere, the State makes a small showing in mining. The mines are principally surface diggings, comparatively few quartz mines being worked. The product has been entirely of gold. We are unable to obtain statistics from all over the State, but of Grant county the *News* has gathered a good deal of information and apparently reliable figures: A little more than 20 years ago the gold mines of Grant county were discovered by chance. A company of men from northern California who were on their way to the then famous mines of Salmon river, Idaho, camped for the night on Pine creek, and some of their number found gold on the creek and staid to prospect more thoroughly. A little investigation convinced them that the mines of the vicinity were very rich, and in a short time Canyon creek was alive with men. The importance of this discovery to Grant county and to eastern Oregon can hardly be estimated. At the date of the discovery this county was a howling wilderness, roamed by the fierce Umatilla and crafty Snake Indian. Now it is the home of miners, farmers and stockmen.

For twenty years a stream of gold has been steadily pouring out of the county. The total output for these twenty years has been enormous, yet all attempts at estimating the amount are guesswork. Of late years much of the mining has been done by Chinese, who are very reticent concerning their operations. The placer mines of Canyon creek were among the first to be worked, and have yielded more of the precious metal than any other creek in Oregon. At one time there were 5,000 men at work on the creek, and wages were very high then, so that the yield must have been large to pay expenses. The creek bottom, from hill to hill, as well as parts of the "rim," has been worked for six or seven miles. At present the principal work is being done by Chinese, near the mouth of the creek. There are probably 150 mining on the creek yet. It is impossible to tell how much gold they have taken out during the year, but is estimated at \$100,000.

The history of Dixie Creek is similar to that of Canyon Creek. It has been worked in the same way and has yielded largely. A Chinese merchant stated some time ago that he had handled \$400,000 that was taken out by his countrymen. At present there are about 35 Chinese at work upon the creek, near Prairie City. It is estimated that they have taken out at least \$25,000 during the year. The quartz mines near the head of the creek have attracted much attention during the year, although most of the work done has been applied in prospecting and testing the various lodes. Three arastras have been at work during the season. Every ton of quartz that has been crushed during the year has paid over \$20 to the ton; some of it as high as \$75 to the ton. Ore has been crushed from 5 lodes and work has been done upon 13 during the year. Most of the rock ground has been taken from Starr & Settlemier's ledges. Yield of quartz mines during the year, between \$11,000 and \$12,000. Number of men engaged in quartz mining, 16. Number of claims filed for record, 33.

On Granite creek the famous Monumental mine, with its splendid mill, is lying idle, but there is said to be reason to believe that it will be started up before long. Work is being done upon 20 mines, although little or no rock was crushed during the year. Ore has been worked from 18 mines in the district at various times. During the year 27 quartz mines were recorded from this district; part of them are on Onion creek. Placer mining has been more active on the creek during the year. There are about 140 men engaged in mining there, 30 of whom are white men and the rest Chinese. The Chinese are exclusively engaged in placer mining; the white men largely so. Sixteen hydraulics were operated during the season, and are estimated to have yielded \$30,000. All other mines, \$35,000.

The mines at Marysville are not situated on a creek, like most placer mines, but consist of a rolling bench at the foot of a mountain. Several acres of surface have been washed off and paid well. Including Pine creek and Quartz gulch close by, there are some 15 white men and 12 Chinese engaged in placer mining. Five hydraulics are operated, employing 10 or 12 men. Estimated yield of hydraulics, \$10,000. Other placer mines, \$3,000.

On Olive creek considerable prospecting for quartz has been done. Eight claims were recorded during the year. Three hydraulics were operated during the summer and took out about \$5,000. There are about 15 white men and 20 Chinese engaged in mining on the creek and in that vicinity. Estimated yield for the year, \$13,000.

Spanish gulch is situated near the western edge of the county, and appears to be outside of the regular mineral belt, which extends through the county from southwest to northeast. Like all the placer mines of the county, it has seen its best days. At present there are three hydraulics operated there during the season, giving employment to seven white men. The yield for the year is placed at \$3,000.

On Elk creek 30 or 40 Chinese took out \$10,000, and a few white men \$5,000.

The number of men engaged in mining in Grant county during 1882 was as follows:

Canyon Creek.....	165
Granite.....	140
Dixie.....	60
Olive.....	35
Marysville.....	27

Elk.....	40
Miscellaneous.....	25

Total.....497

Number of quartz veins located and recorded in the office of the County Clerk during 1882: Gold and Silver—Granite Creek district, 27; Elk Creek, 8; Olive Creek, 8; Dixie Creek, 33; Canyon Creek, 1; Quinn River, 6. Total, 83.

Copper—Dixie Creek, 1. Cinnabar—Birch Creek, 2; Riley Creek, 1. Total, 3.

Placer claims recorded during the year—Granite, 2; Olive, 2; Elk, 4; Canyon, 5. Total, 13.

One ledge of marble has been located on the South Fork.

Yield of Grant county mines during the year 1882:

Canyon Creek.....	\$110,000
Granite.....	65,000
Dixie.....	42,000
Olive.....	19,000
Elk.....	15,000
Marysville.....	13,000
Spanish Gulch.....	3,000
Miscellaneous.....	10,100
Total.....	\$271,000

WYOMING.

Although Wyoming does not figure in the table of bullion production of the United States, there are mines there, and some parts of it are said to be exceedingly rich in gold and silver. Mention should be made of the once abandoned but now again prosperous mining country known as South Pass, Atlantic and Miner's Delight, lying to the east and south of Wind river range of mountains, and about equidistant from Green river station on the U. P. R. R. and old Fort Washake to the east of Wind river and in the Wind River valley.

Miner's Delight mining district, the oldest mining camp on the hill, was discovered in 1876, and was for a long time worked more for its placers than for quartz. It is situated on the west and north of Beaver creek, and extends to Atlantic gulch and Fort Stambough on the west, to the Sweetwater river on the south and east, and includes in its territory what were in former times good placer diggings known as the Strawberry mines; also some very valuable quartz mines to the north of Stambough, among which may be mentioned the Miner's Delight mine, named for the district, the Young America, Mozart, Peabody, Hidden Hand and many others of minor note.

Probably no mining district in Wyoming has a greater number of locations, or a greater amount of work done on them than has Atlantic district. A sanguine correspondent asserts that within a year, or even less, this district will witness a boom not unlike Leadville or even Wood River. All the mines in this district are at an altitude of from 8,000 to 9,000 feet, and all of them also show ore in greater or less quantities. Here are the Buckeye, Cariboo, Old Dominion, Sorelle and Perkins, Red Jacket, Duncan and others.

The South Pass district, adjoining Atlantic on the west, are the Washington, Hope, Doc, Blair, Carissa, Young America, Carrie Shields and a host of others, all good properties lying idle for lack of funds with which to develop them. The same correspondent to whom we refer says: "All that is wanted to make this a second Comstock mining country is capital in the hands of parties who will use it judiciously, and I trust that in less than a year men of capital will become mindful of the fact that a mining country with the facilities this section has should not remain idle."

DAKOTA, ALASKA AND MEXICO.

This year Dakota yielded \$2,855,127, while in the previous year it yielded \$3,550,950. Dakota has been producing for the past six years. So far the productive mines consist of the little group at Black Hills. Recently most of these properties have passed under the same control, and this probably accounts for the falling off in the production in the past two years. The yield of Dakota was the largest in 1880, when the total was \$4,123,000.

Alaska does not ent much of a figure in the table of bullion product, yet she has several good mines about Harrisburg and that region. Other mining regions are being opened also. The recent announcements of discoveries on the headwaters of the Yukon river may possibly attract in the spring a crowd of prospectors who will thoroughly search the country about the new find. The season is so short in Alaska that the mining development of the country will be comparatively slow.

A good deal of attention is now being paid to mines in Mexico by Americans, but mining there is attended with many difficulties not experienced in more enlightened countries. Still its mines are attracting many persons, especially into those parts of Mexico where the railroads will run.

Lower California mines have never been profitable, and comparatively little mining is done there. There is an extensive copper belt in the country, however, which will no doubt before long be taken hold of and developed.

SENATOR ARTHUR GORMAN, of Maryland, presided over the United States Senate during the temporary absence of Vice-President Davis. Less than 20 years ago Gorman was a page in the Senate.

The "Garland" Patent SEWER GAS TRAP

Is a sure shut-off against Sewer Gas and Back Water. The Loaded Metal Ball Valve is slightly heavier than water. This Trap can be put in at small expense, and is warranted to give satisfaction. Highly recommended by leading Architects and Plumbers. Used in all new, first-class buildings in San Francisco, including Phelan Block. For sale by all dealers in Plumbers' Goods, and by the "GARLAND" IMPROVED SEWER GAS TRAP MFG CO., 1301 Broadway, Oakland, Cal. Coast Rights for sale.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER.

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT OUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

No. 252 Market Street. Elevator, 12 Front St., S. F. Telephone No 658.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., PATENT AGENTS.

THE ROLLER ORE FEEDER.

Patented May 23, 1882.

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required. In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

Of Interest to Miners.

During the next few months we intend giving to the readers of the MINING AND SCIENTIFIC PRESS a series of valuable illustrated articles of special value. Among these may be mentioned a series of articles now in course of preparation on "Timbering in Mines," which will be very freely illustrated. This will give the methods in vogue on this coast, as well as those commonly practiced elsewhere. A series of articles is also being prepared on "Blasting in Mines," which will also be illustrated. This will be of great practical interest, containing, as it will, many details of every-day use to the miners. It will treat of the various methods of preparing blast holes, blasts, etc., the tools used, the explosive agents and kindred subjects.

In addition to these articles, which will be continued through several numbers of the PRESS, we are preparing a special mining map of British Columbia, with a description of the geology of the region and of the mining districts.

A map of the mining districts of Alaska will also be given, showing the location of the quartz mines now being worked. It will also show the course of the Yukon river, where the recent finds of placer mines were made, and where it is expected some rich developments will be made next season.

We have, too, in course of preparation a map of some of the Montana districts, and one also of the various mining districts of southwestern Nevada, along the line of the Carson and Colorado railroad.

It is intended to more fully illustrate the PRESS than heretofore, and with appropriate engravings. Such of the mechanical appliances of mining or metallurgy as may be practical in their nature we propose to illustrate and describe from time to time as occasion offers.

It is the aim of the publishers of this journal to keep pace with the progress of the mining industry. The mountains of the whole western side of the continent are now hunted over by the adventurous prospectors. New mines are being found every day, and new works are being put up. The MINING AND SCIENTIFIC PRESS has kept track of this business for 20 years, and been with it in its ups and downs. Its best efforts have always been with the prospector and working miner, and will continue to be so.

It has been our object to cull from every source such things as would be of practical value or interest to the class of readers with whom we are identified, and these efforts have been appreciated, we trust.

The PRESS has the satisfaction of knowing that its columns have never been lent to bolster up any scheme to fleece unwary stockholders, and that it has persistently upheld legitimate mining. Now that legitimate mining is in the ascendant, we feel that we have done our share in the good work.

We can of course do nothing without the co-operation of the mining community. While already possessing among our subscribers a large proportion of the progressive miners of the coast, there are new men in the business who may not be familiar with the merits of this journal. To these others familiar should present its advantages and call their attention to the desirability of becoming subscribers. It will be a mutual advantage. The more full our patronage the better paper we can make. We trust these words will not fall unheeded, but that they will result in material addition to our lists. We feel no hesitation in presenting our claims, feeling as we do that it is but justice to ourselves to call attention to them occasionally.

ABOUT MINING LOCATIONS.—A question which has perplexed locators of mining claims for some time, and on which there has been a difference of opinion among claim owners, has been settled by the United States Land Commissioner at Washington. The question asked was this: "Is a location made on a quartz lode or ledge on the first day of January, 1882, subject to relocation on the first day of January, 1883, provided the required assessment work has not been done for the calendar year of 1882?" To which Commissioner McFarland replied: "It is not. The locator of a claim initiated on the first day of January, 1882, has until January 1, 1884, to complete the first assessment work; which work when done would hold the claim until January 1, 1885."

GUSTAVE DORE, the famous French painter and designer, is dead. Dore caught cold Friday when returning home from a source. On Saturday inflammation of the throat set in, and despite every effort it was impossible to arrest its progress, and he expired at 1:30 p. m.

Alluvial Gold in California.

The State Mineralogist has arranged on a series of microscopic slides the various forms of gold as collected in hydraulic, placer and drift mines in California, with associate minerals found in "cleaning up" the sluices. These forms of gold are very curious, some of them, and of great interest to the miner. The slides are arranged to serve as objects to illustrate the description in the report of the State Mining Bureau.

One slide showed gold crystals after stibnite (?) from the Lake mine, Napa county, California. Several pans of dirt were taken from the gulch, washed down in a miner's pan to a small quantity, a portion of the mercury added, the mercury separated without rubbing and boiled in nitric acid, these pseudomorphic crystals remained. An attempt was made to produce similar crystals by treating precipitated gold in the same manner, but without success.

The gold from the Beveridge mine, Inyo county, was shown as having been rolled into cylinders under the smelter while being crushed.

The placer gold from upper San Joaquin river, Fresno county, California, is fine and free from coating, except to a slight degree on some of the pieces. It shows a tendency to crystallize.

Placer gold from San Luis Obispo county was shown very pure and free from coating.

Placer gold from the shores of Mono lake, Mono county, California, is remarkably pure and free from coating. It amalgamates perfectly and immediately on being brought in contact with mercury.

Placer gold from Chile gulch, Calaveras county, is in a cryptocrystalline state not easy to account for. Many of the grains inclose quartz, which would seem to indicate that it has its origin in some quartz vein in the immediate vicinity. It differs from ordinary placer gold, and may have been collected by mercury and overheated in the retort.

The electron we have already referred to in previous numbers of the MINING AND SCIENTIFIC PRESS.

Another piece is a typical specimen of coated or "rusty" gold, Red Hill hydraulic mine, Butte county. All attempts to collect such gold by amalgamation results in failure; for this reason a large proportion of the placer gold, and especially that from the ancient river beds, is lost to the world. The loss is so great, and the matter so serious, that miners, inventors and scientific men should attempt to devise some plan by which such gold may be saved.

Another piece is rusty or coated gold from a large deposit of tailings below Oroville, Butte county. The particles of gold are not in the same extent coated, but that all are more or less so.

The placer gold from the Bonanza hydraulic mine, Gold Run, Placer county, is considerably coated. This gold was collected in "crevicing."

One specimen of placer gold was shown coated with silica by pressure and friction, from the Blue Lead bedrock, below the gravel, Chalk Bluffs, Nevada county.

Coated placer gold, with pyrite and magnetite, from Nevada county, is among the specimens.

Another is a piece of hydraulic gold, amalgamated and boiled in nitric acid, by which the mercury was dissolved. The product is beautifully crystallized. The gold used was amorphous.

One piece showed gold precipitated from solution of sesquichloride by solution of protosulphate of iron.

One slide showed precipitated gold amalgamated and boiled in nitric acid.

Gold from the Spring Valley hydraulic mines Butte county, was in the form of amalgam, from which the mercury was volatilized by heating to redness in a porcelain capsule.

Concentrations from the Spring Valley hydraulic mine, Cherokee Flat, Butte Co., show platinum and iridium.

Concentrations from placer washings, Chiquita Joaquin, Fresno county, contain zircons with gold; curious as showing gold in two conditions—as pure gold or nearly so, and as electrum, a natural alloy of gold and silver.

Gen sand (so-called), from Lower Gold Bluffs, Humboldt county, contains gold, platinum, magnetite, chromite, quartz, zircons and red crystals. It is the result of natural concentration by the action of the waves on the ocean beach.

Concentrations from the Spring Valley hydraulic mine contain zircons.

Sands concentrated from placer mines, in Amador county, contain zircons.

In the dime sands of San Francisco, all, or nearly all, of the grains are rounded. In this deposit, which is quite extensive near the city of San Francisco, there are beds of iron sands in varying states of decomposition, showing how some sand stones are mottled and become shaded in process of induration.

In the fine sand from the Colorado desert, San Diego county, the grains are rounded by the action of both water and wind.

In specimens from the fine sand from the Spring Valley hydraulic mine all the grains are angular.

Fine quartz sand from the Polar Star hydraulic mine, Dutch Flat, Placer county, shows all the grains to be sharp and angular.

Another microscopic slide showed placer gold with globular pyrite in the form of sand from Last Chance mining district, Placer county. This gold is but slightly coated. The small concavities are in some cases coated with silica, and some grains show the pyrite attached. The gold is remarkably fine, probably the most so of any in the State, being .996 fine. The pyrite sand is very interesting when examined microscopically. This association is rather rare. The exact locality is Section 34, township 15 north, range 12 east, Mount Diablo meridian.

Miner's Combination Tool.

John Jones, of Oregon city, Oregon, has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency a combination tool for the use of miners in their operations with blasting fuse. For handling fuse in preparing it for a blast an ordinary pen-knife does not answer the purpose well. This invention is intended to provide a tool to split the fuse either lengthwise or crosswise, to cut it off squarely from the coil, to press its end to receive the cap, and, finally, to press the cap tightly upon it. The tool is in shape somewhat like a pair of pliers, the points or jaws of which are formed, one flat and the other into a blade, constituting the splitting mechanism, and the flat jaw having upon its rear part a small projection formed into a cutting edge, which, with that portion of the blade which meets it, constitutes the cutter. Behind the pivot-point the meeting handles are formed with grooves adapted to fit around and press the end of the fuse, and also with other grooves having ribs adapted to fit around the cap and press it tightly upon the fuse when fitted upon it.

Blasting fuse is ordinarily a tube filled with some combustible material. In order to get at this composition to apply the match so that it will readily ignite, the protecting tube is split lengthwise at one end. Sometimes, where no blasting cap is employed and the explosion is effected by direct contact with fire, it is necessary to split or cut the sides of the tube crosswise, so that the fire when it reaches these cuts may issue forth to produce the explosion. One side of the plier has its point or edge made flat upon its inner surface, while the other side has its edge made in the shape of a blade, the cutting edge of which is adapted to be brought down upon the flat surface of the other jaw. By this construction the fuse may be split or laid open, and may be cut crosswise without entirely cutting through it. Upon the flat jaw near its rear part is a projecting jaw, which is ground to a cutting edge, and forms, with the blade of another jaw, a short cutter. In this the fuse may be easily severed from the coil or cut into desired lengths. Behind the pivot-point on the inner side of the two handles, which are of some width, are cut grooves, which, when the handles meet, form a hole or die. In these grooves are formed ribs or beads. When the cap is fitted upon the end of the fuse it requires to be pressed tightly, making it secure and water-tight, so that it will not be damaged when used in wet holes. The handles are opened and the cap fitted in the grooves, which are then brought together and pressed tightly around it. The heads press into it and form encircling dents which hold it securely to the fuse. Behind the grooves are others, smaller, which are made to fit over the end of the fuse and by compressing it prepare it to receive the cap with ease.

The annual meeting of the American Institute of Mining Engineers will be held in Boston, beginning February 20, 1883. Volume X of the transaction will soon be distributed.

Mining Notes from Nevada.

L. N. Murry, a well-known Comstock miner, came in from Nevada this week. He reports mining operations on the Comstock as at nearly a standstill. But few men are employed at any of the mines, and the prospects look very gloomy. Selling out and leaving is the order of the day in Virginia City and Gold Hill. The "Northern Belle" mines, in Esmeralda county, show some activity, there being 85 men employed in and around the mines; some very good ore is being taken out; the lower levels show fine veins of medium grade ore. Some very rich prospects have been struck in various parts of the country, but it is hard to get capital to take a hand and help develop new mines, as they have been so often out of pocket by such operations. In Garfield district, near by, several mines have been partially opened, which, in nearly every instance, show good pay ore, and sufficient is produced to keep two custom mills running day and night. A company has been formed, which will at once commence the erection of another mill. About 200 miners find employment in the district, working either on shares or by the day.

The "Alexandria" mines, at Grantsville, Nye county, Nev., are doing but little, although there are vast quantities of low-grade ore in sight, but the high price of fuel and the low price of the bullion produced at these mines keep the company from pushing their mining operations.

The Manhattan Mining Company, at Austin, Lander county, are making about their usual monthly shipments. They are not increasing their force of miners, however, owing to the low price at which their bullion is sold in the market. Mr. Murry is of the opinion that the Garfield is the most promising district in the State, and proposes to erect a custom mill at that point in the spring.

News in Brief.

It is authoritatively stated that the Prince of Wales and suite will visit Canada the first week in March, remaining until after the meeting of the Science Association.

About 40 lives were lost by the explosion at the Giant Powder works, near West Berkeley, on Sunday.

TRAIN robbers on the C. P. R. R. were foiled by the bravery of the express messenger Ross, who kept them at bay until time for another train to arrive, when they rode off, robbing only the train men.

A woman, laboring under religious insanity, in Milwaukee, killed her three children, oldest seven and the youngest 18 months, in the most brutal manner, literally cutting them to pieces and completely disemboweling them. She took her arrest very calmly, stating she had read in the Good Book that it was her duty to sacrifice her children.

THE CARTWRIGHT MINE.—Doak & Auderson, proprietors of the Champion lode, in Fresno county, have their new 10-stamp mill running on custom rock at present, but will soon start it on their own rock, of which they have quite a lot on the dump, and enough good paying ore in sight to keep the mill running for six months. They have three of Hendy's concentrators in use. All the machinery works to a charm.

Does Advertising Pay?

The Portsmouth (Virginia) Times says: It is sometimes questioned by merchants whether advertising pays. The question will hardly bear discussion in the light of the following facts, rates for transient advertisements being figured: "The Chicago Tribune," it is said, for a column a year receives \$26,000. The New York Herald receives for its lowest-priced column \$39,723 and for its highest \$349,000. The New York Tribune for its lowest \$29,764 and for its highest \$95,648—and these papers are never at a loss for advertisements to fill their columns. Their patronage comes not from any desire to assist the respective parties, but from business men who find it profitable to advertise."

A firm of manufacturers in Philadelphia placed an advertisement in a journal as an experiment. As they were economical Quakers, they commenced sparingly. Within three months their advertisements were running in seven different publications, and there is no question with them about its paying. As well might an enterprising firm try to save postage as the cost of advertising. Customers go to those who most persistently extend them an invitation. Judicious advertising pays a hundred fold.—Exchange.

Recent Contributions to the California State Mining Bureau.

(Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY G. HANES, State Mineralogist.)

- 4475. Root, resembling an owl's head—Found on the beach, San Francisco bay, near Marin. J. Z. Davis.
- 4476. Silver ore showing wire silver—Belle of Butte mine, Butte, Montana.
- 4477. Crude Ozocerite—Southern Utah. J. R. Scoupham,

Esmeralda Coal Fields.

Some ten years ago, while prospecting for mineral bearing quartz, in the vicinity of what is known as the Washington district, croppings of coal were found which promised to develop into something of importance. Samples were in Aurora, and although they were considered valuable, but little was done toward a further development. E. C. Smith, who has taken a great interest in the matter, recently visited Carson, and informs the *Index* that the deposit is about ten miles southeast of Pine Grove, in Esmeralda county. It promises to prove quite extensive, and will furnish fuel for all of Mason valley without any trouble. The coal has been tested in ordinary coal stoves, and proves very nearly equal to the Rocky mountain article. It burns readily and leaves comparatively little residuum. The stratum already penetrated by a shaft of forty feet is fifteen feet in thickness, and the coal is easily mined. If this coal discovery is properly developed it will greatly reduce the expense of fuel in Mason valley. Wood is rapidly becoming scarce and dear. In some places in the valley it is necessary to go twenty-five miles or more to the mountains for wood, while the coal can be delivered in all parts of the valley at a freight charge of not much, if any, over five dollars per ton. Mr. Smith is the owner of this property, and looks forward toward realizing a handsome profit therefrom in the near future. We are glad to congratulate him and the people of Mason valley over this luckily found deposit of good fuel. The mine is about twenty miles from Pizen Switch.—*Esmeralda Herald*.

The London *Times*, on the burning of the Newhall house, at Milwaukee, says: It is a reproach and shame to modern intelligence that nearly a hundred lives were lost, in sight of a crowd eager to aid, from want of effective mechanical appliances.

The California representatives are very much annoyed at the action of the Ways and Means Committee in refusing them a hearing on the questions in relation to the tariff of interest to their section of the country. They promise to make a fight for their interests when the bill comes up in the House.

Know

That BROWN'S IRON BITTERS will cure the worst case of dyspepsia.

Will insure a hearty appetite and increased digestion.

Cures general debility, and gives a new lease of life.

Dispels nervous depression and low spirits.

Restores an exhausted nursing mother to full strength and gives abundant sustenance for her child.

Strengthens the muscles and nerves, enriches the blood.

Overcomes weakness, wakefulness, and lack of energy.

Keeps off all chills, fevers, and other malarial poison.

Will infuse with new life the weakest invalid.

37 Walker St., Baltimore, Dec. 1881.
For six years I have been a great sufferer from Blood Disease, Dyspepsia, and Constipation, and became so debilitated that I could not retain anything on my stomach, in fact, life had almost become a burden. Finally, when hope had almost left me, my husband seeing BROWN'S IRON BITTERS advertised in the paper, induced me to give it a trial. I am now taking the third bottle and have not felt so well in six years as I do at the present time.
Mrs. L. F. GRIFFIN.

BROWN'S IRON BITTERS will have a better tonic effect upon any one who needs "bracing up," than any medicine made.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS. All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

NO. 1.—The most Powerful Explosive Compound now in use here.
NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much finer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro-Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

FEATHERING PADDLE WHEEL.—Chas. Megow, San Francisco, California, assignor of one-half to John L. Markel, of same place. No. 269,948. Dated January 2, 1883. This invention relates to a new and useful propeller wheel; and it consists in centrally-mounted revolving wheel, having around its outer circumference a number of swinging blades or fans having peculiar stems engaging with sliding frames set in the wheel. The wheel is mounted in a hollow casing, having a portion of its bottom cut away to permit the blades of the wheel to emerge therefrom and be exposed for a short distance. The inner surfaces of the casings have grooves in which pins or studs on the sliding frames travel, and these grooves are so made that by means of certain switching devices, the pins are deflected from one groove to another to lower and elevate the frames, whereby the blades are turned at right angles with the wheel just after they emerge from the casing, and are again turned in line with the wheel before they re-enter the casing. The object of this invention is to provide an effective propeller wheel, which may with advantage be applied to steam vessels, to which, on account of its simplicity, durability and effectiveness, it is peculiarly adapted.

MINER'S CANDLESTICK.—John Jones, of Oregon City, Or. No. 270,316. Dated January 9, 1883. This invention relates to a novel candlestick or holder specially adapted for the use of miners; and it consists of a prod or point pivoted or hinged in the end of a safeguard, and secured in position either in line or at right angles with said guard by a swinging clasp. The prod is pivoted with a hook near its point, and a spring-rig for the candle is secured to the device. The object of the invention is to provide a candlestick or holder, which, when not in use, may be carried in the pocket, and when in use, may be readily inserted in any convenient timber, or hung from a projecting point, and is therefore particularly adapted for use in mines.

IRON AND ILLUMINATING STAIRS.—Peter H. Jackson, San Francisco, California. No. 269,863. Dated Jan. 2, 1883. This invention relates to certain improvements in the construction of iron and illuminating stairs. And it consists in so forming the risers of the stairs that the inner edges of the treads or steps are supported upon their projecting flanges, no intermediate support being necessary, and a part of the finish under the projection of the step is supplied. The molding which forms the finish of the front edge is partly formed upon the edge of the step and partly upon the riser. The bottom riser is made of the full depth, and the grade of the street is conformed to by a tapering filling-in piece which rests upon the lip of the riser, its upper edge supporting the inner side of the tile.

HEADER.—Abraham Miller, Gridley, Cal. No. 269,951. Dated January 2, 1883. This invention relates to certain improvements in headers; and it consists of the header-frame supported upon bearing-wheels in the usual manner, and having a tongue to which the team is attached. This tongue has its front end hinged or journaled to the lower part of the frame below the axles of the bearing-wheels, and may be raised or lowered at this point, the object being to relieve the raising and depressing lever from strain and to balance the action of the driving-gears.

CANNING APPARATUS.—Richard Wheeler, Alameda. No. 270,529. Dated January 9, 1883. This invention relates to an apparatus for putting up all sorts of hermetically sealed goods in an inexpensive manner, and it consists in the employment of a water reservoir with a heater beneath and a series of separate inclosed chambers above, through which steam or hot air is allowed to pass and surround the cans or glass jars containing the substance to be cooked, the cans or jars being placed in the chambers. These chambers are arranged in series, so that either series may be withdrawn at will.

TWO-WHEELED VEHICLE.—Gilbert A. Wright, Leven H. Fowler and Samuel Shaw, Napa City, Cal. No. 269,982. Dated Jan. 2, 1883. This invention relates to that class of two-wheeled vehicles commonly known as "carts," and it consists in a novel arrangement of the shafts with respect to the axle, and of the body with respect to the shafts.

GRAIN SEPARATOR.—Daniel Best, Albany, Oregon. No. 270,001. Dated January 2, 1883. This invention relates to certain improvements in grain separators, and it consists in mechanism by which the amount of shake given the shoes is regulated, and the joints always kept tight and prevented from rattling.

FAUCET.—John L. Berry and Shadrack Gladney, Antelope, California. No. 269,912. Dated January 2, 1883. This invention relates to a new and useful improvement in faucets; and it consists in certain details of construction.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

N. H. HARGSON—Plumas county.
E. T. THURSTON—San Francisco.

For the Ladies.

A GOOD FAMILY PAPER.—The Illustrated Ladies' Home Journal, published by Dewey & Co., is a valuable monthly, sixteen-page paper, for women everywhere. Several pages are devoted to fashion, in which the most desirable styles for women and children are illustrated with such careful and explicit directions for cutting and trimming that rural wives and daughters may dispense with dressmakers, and yet dress as stylishly as their sisters of the city. Besides fashions, it has entertaining and instructive miscellany for all ages. It is printed on Dewey & Co.'s fine paper, is beautifully illustrated, and, altogether, a very desirable fireside friend.—Flora Kimball, in California Patron.

STOCK DIVIDEND.

At a Meeting of the Directors

—OF THE—

Gila Silver Mining Company,

Hold this day, a Stock Dividend of Two Shares for each outstanding share was declared, deliverable on and after February 1, 1883.

J. T. McGOOGHEGAN, Sec'y.

NOTICE OF DISSOLUTION.

OFFICE OF THE

South Comstock Gold and Silver Mining Company, No. 309 California Street, San Francisco, California, January 18, 1883.

Notice is hereby given that, pursuant to the provisions of Title Six of the Code of Civil Procedure of the State of California, a meeting of the STOCKHOLDERS of the SOUTH COMSTOCK GOLD AND SILVER MINING COMPANY, a corporation organized and existing under the laws of the State of California, will be held on MONDAY the FIRST (5th) day of FEBRUARY, A. D. 1883, at the hour of TWO o'clock P. M. at said Company's office in room No. 4 of premises No. 309 California Street, in the City and County of San Francisco and State of California, to consider and vote upon the question of the voluntary dissolution of said Corporation and such other business as may properly come before said meeting.

By order of the President and Board of Trustees,
J. M. BUFFINGTON, Secretary.

DIVIDEND NOTICE.

OFFICE OF THE

Bulwer Consolidated Mining Company.

San Francisco, January 25, 1883.

At a meeting of the Board of Directors of the above named Company, held this day, Dividend No. 15, of five cents (5c) per share, was declared, payable on Monday, February 12, 1883. Transfer books closed on Friday, February 2, 1883, at 3 o'clock P. M. This dividend is payable at the Farmers' Loan and Trust Company in New York on all stock issued there, and at the office in this city on all stock issued here.

WM. WILLIS, Secretary.

OFFICE—Room No. 29, Nevada Block, No. 309 Montgomery Street, San Francisco, Cal.

PATENTS

Bought and Sold for INVENTORS and handled in UNITED STATES and EUROPE.

Profitable Investments in Valuable Patents made for Capitalists by

GEORGE B. DAVIS,

Room 14, 320 California St. (over Wells & Fargo Bank), SAN FRANCISCO, CAL.

The Pacific Coast offers a good market for useful Inventions.

BUY LAND

Where you can get a crop every year; where you will make something every season; where you are sure of having a crop when prices are high; where you have a healthy place to live; where you can raise semi-tropical as well as other fruits; where you can raise a diversity of grain and vegetables and get a good price for them. Go and see the old Reading Grant (in the upper Sacramento Valley), and you will find such land for sale in subdivisions to suit purchasers—at very low rates and on easy terms. There are 12,000 acres at from \$3 to \$30 per acre, including pasture, vine, fruit land and grain land. Will sell the whole tract at a great bargain. Send stamp for map and circular to EDWARD FRISBIE, proprietor, (on the Grant), Anderson, Shasta Co., Cal.

Inventors' Institute

—OF—

CALIFORNIA,

321 California St., San Francisco.

Patented Inventions sold upon Commission. Agencies everywhere. Send stamp for Circular containing terms etc., or call at rooms of Institute for information.

QUICKSILVER.

THE CELEBRATED A BRAND.

Shipped Direct from the New Almaden Mine, New Almaden Station, Santa Clara Co., Cal.

For sale in any quantity. Trademark A on top of Flasks secured by United States Patent, and registered. Flasks contain 7 1/2 lbs. Quicksilver. Weight and purity guaranteed.

CARLOAD LOTS will be shipped from San Jose, f. o. b., for Nevada, Arizona, New Mexico, Montana and Idaho or Utah, or delivered at Pacific Mail Steamship Co.'s wharf, and Depot of S. F. R. R. Co., San Francisco, without charge. Railroad rates from San Jose are the same as from San Francisco.

J. B. RANDOL,

P. O. Box, 1073. 320 Sansome Street, S. F.

Carson and Colorado Railroad.

(NARROW-GAUGE.)

The Company announces the completion of its line March 1, 1882, to CANDELARIA, Columbus Mining District, Esmeralda Co., Nev., 158 miles from Mound House (Junction with Virginia and Truckee Railroad).

STAGE CONNECTIONS.

At Hawthorne with U. S. Stage Company's daily coaches for Aurora (26 m.); Bodie (37 m.); Lundy and Bridgeport. At Luning (125 miles from Mound House) with Gilmer, Salisbury & Co.'s tri-weekly stages (leaving Tuesday, Thursday and Saturday mornings) for Grantsville, Belmont and Tule.

At Belleville (150 miles from Mound House) with Beloville and Independence Stage Co.'s stages for Benton (40 m.), Bishop Creek, Big Pine and Independence. At Candelaria, with U. S. Stage Co.'s stages for Columbus (8 m.), Silver Peak, Montezuma, Alida Valley, Gold Mountain, etc.

THROUGH TICKETS

To the above points for sale at San Francisco, Sacramento, Reno, Carson and Virginia R. R. Ticket offices.

This is the direct and natural route for Passengers and Freight, to points in Southern Nevada, Mono and Inyo counties, California. The line, laid with steel rails and redwood ties and equipped with new and first-class rolling stock, is penetrating new and most promising Mining Districts which are now attracting deserved attention throughout the country.

For information on through freight rates apply to H. M. YERINGTON, D. A. BENDER, Gen'l Supt. Gen'l Freight & Pass. Agent, Carson, Nev.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Small Sizes made in Sections not to Exceed 300 lbs.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

-OR-

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ore is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

Publishers.

SAN FRANCISCO, SATURDAY, FEBRUARY 3, 1883.

VOLUME XLVI
Number 5.

Operating Pumps in Mines.

Mr. John Huffer, of Jacksonville, Oregon, has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency a new method of operating pumps in mines or deep wells, where the pumps are located on different levels or stations. The object of the invention is to furnish means for operating all the pumps upon the various levels or stations at the same time by the application of the original power, which, by certain mechanical devices, is transmitted throughout the entire system.

Across the top of the shaft is suitably journaled the driving shaft, upon which is a pulley on which is firmly clamped a flat wire cable. This cable is clamped to its center at the top of the pulley to prevent slipping, as its ends are loose and swing down upon each side over the face of the pulley. This power pulley does not make a complete revolution, but oscillates, that is, it revolves part way and then back.

At the first side station or level is journaled a horizontal shaft, carrying upon one end a double-faced pulley. Upon the outer of these faces is clamped at the center and underneath the pulley another flat cable, the ends of which pass about the face of the pulley at its sides, and extend up to connect with the lower ends of pieces of round cable already attached to the flat cable of the power pulley, thus making a connection with the upper pulley. In the pieces of round cable connecting the flat cables are placed set screws or links, whereby the cable connection can be tightened and adjusted. Over the other face of the pulley at the station is another flat belt connected in a similar manner to that already described, with the pulley at the next station by similarly arranged belts. Each level is connected with the one above in this way, and at each station is a pump.

The shafts of each of the sets of pulleys have pinions at their ends, these pinions engaging with a rack, either formed with or attached to the piston rod of the pump. Power is applied to the main driving shaft and pulley at the surface to give the pulley an oscillatory motion. This is transmitted through the continuous belt or cable connections to the pinions at the several stations, and by means of these pinions the piston rods of the pumps are moved back and forth to operate the pumps. The pumps may be single or double-acting, or two single-acting pumps, one at each end of the rack, may be used.

The pumps may be operated at any angle desired, by clamping the flat cables at suitable points upon their pulleys, and by the interposition of guide pulleys the power may be transmitted to them in any location, as in a tunnel or down another shaft. The general principle of operating a series of pumps simultaneously is not new, but the other devices differ from Mr. Huffer's. The vibrations of the cable is provided for, and also the stretching of the cables.

The Chico Record says: An industrious miner from the Butte Creek region came to town this morning with over \$1,600 worth of gold dust, which he deposited in the Bank of Butte County. He said that the miners along the creek are now idle on account of the scarcity of water, but they hope to be at work when the spring rain sets in.

In the Arizona Legislature the bill to pay Prof. Church the expenses he claimed to have incurred as Commissioner to Denver was defeated.

Mine Timbering.

On the Comstock the material enclosing the ore bodies in bonanzas is of a very unstable character, and involves an immense cost in timbering. The ore bodies frequently have selvages of clay of considerable thickness. The whole is soft and yielding, and owing to the clayey nature swells on exposure to the air, exerting an enormous pressure. The extraction of such immense bodies of ore and the opening of such extensive chambers with insufficient support of the country rock or vein matter induce large movements of the surrounding masses. Great caves of ground from old stopes occur. The difficulty of sustaining ground of this nature by any method of timbering is not only great in itself, but is much increased by the

timbers that are framed together on rectangular sets four to five feet square, the floors being supported one above the other by posts seven to eight feet high. The two left-hand figures of the engraving illustrate the method of timbering in stopes. They present an elevation and floor of a single set, showing the details of framing. The timbers are usually of 12-inch stuff and square-hewn or sawed. They are formed with much care so that the various parts fit snugly and nicely together.

Drift Timbering.

The method employed in timbering drifts or tunnels is the same as is generally in use in other districts. The timber is, however, all square, varying in size from 8 to 13 inches. Ordinary working drifts, such as those connect-

STOPE TIMBERS.

DRIFT TIMBERS.

large size of the chambers rendered vacant the extraction of the bodies of ore.

Methods ordinarily in use in veins of moderate width and in firm rock were found to be insufficient. To meet the necessities of the case, a method of timbering was introduced, which is said to have been devised by Mr. Diedeshimer, which, though meeting at first with some opposition, on account of its great cost, has been generally adopted, and is used in all the mines on the lode. This consists of framing timbers together in rectangular sets, each set being composed of a square base, placed horizontally, formed of four timbers, sills and iron pieces, four to six feet long, framed together, surmounted by four posts six to seven feet high at each corner, and capped by a framework similar to that of the base. These cap pieces forming the top of any set are at the same time the sills or base of the next set above, the posts, as the sets rise one above the other in the stopes, being generally placed in position directly over those below.

This somewhat complicated system of timbering may also be described, in other terms, as a succession of horizontal floors composed of tim-

bering the main shaft with the vein, are about five feet wide in the bottom, four feet wide in the top and seven feet high. They are usually timbered with vertical sets or frames, consisting of two posts, a cap and a sill or spreader. These posts are mainly seven feet two inches high, the cap three feet nine inches, and the sill four feet nine inches long. These sets are placed from two to six feet apart, according to the nature of the ground. They are covered on the outside with lagging, which is likewise varied according to condition, consisting sometimes of six-inch scantling, in pieces five or six feet long, and placed several inches apart, sometimes of three-inch or four-inch plank, placed close together, inclosing both sides and top, and sometimes the bottom. Lagging, consisting of light scantling, placed several inches apart, is often preferred in heavy swelling ground, as the pressure breaks in the pieces of scantling before effecting the stranger timbers of the tunnel sets. By picking down the intruding clay and relieving the pressure, the more expensive timbers are saved. String pieces, usually of square stuff, or three inches by four inches, are laid in the bottom on the sill timbers, and shod with flat iron one and one-half inches wide by one-fourth inch thick to serve as track for the drift cars, and a footway of two inch plank is laid between the rails.

The two right-hand figures of the engravings illustrate the method of framing the tunnel sets.

Alaska as a Mining Region.

Just at the present time there is some unusual "interest" in the mining prospects of Alaska, brought about, no doubt, by certain vague rumors current of late regarding supposed rich placer discoveries somewhere about the headwaters of the Yukon river. The party that made the trip up the river is one composed of old miners and prospectors, equipped with steamer, boats and canoes, with supplies for three years, and everything in first-rate style. It was expected to remain over winter and do the prospecting this summer, as they would have little time the past summer. It seems somewhat unreasonable that these men, after all the trouble and expense they have been to, would publish abroad the fact of striking rich diggings until at least they had some chance to work them. They were not a lot of "tender-feet," to draw a crowd to a region where they had it all their own way; at least it is hardly probable, under the conditions, the men would "blow" about the discovery. It is best, therefore, to receive with caution stories that may be current.

These views are confirmed by a conversation we had this week with James Williams, a miner who has spent the best part of the last seven or eight years prospecting in the northern country, and who has been in the city this winter, but will return to Alaska on the 20th inst. Mr. Williams has been on the Stickeen river and other British Columbia mining regions, and is familiar with Alaska also, owning claims now at Harrisburg, where the principal mines of Alaska are situated.

In the season, Mr. Williams tells us, there are about 200 miners about Harrisburg. Very little prospecting has been done outside of the camp itself. They know nothing so far of the ledges, but there are a few good paying placer claims. No one knows as yet the extent of the field. The claims are in high banks or benches, and the gravel is from 3 to 20 feet in thickness. The material is a sort of decomposed stuff—a mixture of broken quartz and other debris. Sometimes a reef of quartz will be met with in the gravel bed.

Water is plenty, and is brought to the gravel beds in ditches from the creeks. There is no company furnishing water, the miners bringing it themselves to their claims. The season lasts from five to six months, but varies considerably. It is expected it will commence in May this year.

The miners at Harrisburg take up 200 feet frontage on the hill ground, and 1,000 feet running back. Most of the mines are on the mainland, but there are some on the islands. There are two companies mining on Douglas island.

All the region close around has been taken up. Some little prospecting outside has been done, but it has not paid. The mines are not in a regular gold belt; it does not seem to be a regular wash. The belt cannot be traced at all. Wherever stringers of quartz are found placer ground is met with around it. The quartz and placer ground have to be recorded separately. Four hydraulic nozzles (two of Hoskins' pattern) will be sent up on the steamer that goes this month. These mines are most of them worked by hydraulic process. We shall have more to say about the mining region of Alaska in next week's PRESS.

The work on the Channel tunnel is still going on quietly.

CORRESPONDENCE.

Colorado Notes.

EDITORS PRESS:—Mining is being interfered with somewhat by the recent cold weather and snow, yet many properties, being well prepared for winter, continue their working without any difficulty.

The Red Mountain district, 8 miles from Ouray, in the San Juan country, is not to be deterred by wind or weather, and is developing some fine mines through the snow. This district probably possesses some of the richest mines in the State. In fact, they are striving hard to have it become known as "New Leadville" or "Second Carbonate Camp." It is true they are making some wonderful discoveries for a camp only five months old, three being winter months. Old Leadville miners went in there in December, and are living in tents and prospecting, and

Sinking Shafts Through the Snow.

There are some gray carbonates of lead found associated with galena, but not sufficient to give the camp much notoriety as a carbonate camp. The ores are principally sulphides of lead and copper. While not generally high grade, the ore lies in vast bodies, and probably averages \$50 per ton. Among the mines of this district is the Congress, with an ore body 18 ft. in width, from which 110 tons of ore was taken which netted \$100 to the ton in copper, silver and gold. The Hudson, with a shaft 52 ft. deep, has a body of ore 11 ft. thick, which will run \$90 to the ton. The Yankee Girl is evidently quite a bonanza. It has two shafts, one 42 and the other 50 ft. deep. The former is in a solid body of galena ore 40 ft. in thickness, and no bottom reached yet. This ore nets \$35 to \$50 per ton in St. Louis. The Yankee Girl was sold on the 20th of last September for \$125,000 cash. The D. & R. G. R. R. will, it is expected, extend their line to Ouray next summer, and this camp will be brought into prominence.

The Electric Light

Is being adopted in a number of mines throughout the State. The Silver Cord group of Leadville employ seven electric arc-lamps on its premises, which are pronounced very satisfactory illuminators. The ore-house contains two of these lights, and the ore is sorted with fully as great precision as can be done by daylight. The Iron Silver Mining Co. of the same district are also considering the feasibility of working by the electric light.

It is estimated that a plant such as the Iron Silver Company think of putting up would cost, all told, between \$2,000 and \$2,500, and at that price it would unquestionably prove a beneficial and saving investment to any mining company employing a large force of men at night. The miners of Alma, Park Co., held a meeting on the 4th inst. for the purpose of considering the most effective means of

Exposing All Wild Cat Schemes,

Fostering honest enterprises and preventing unprincipled individuals from employing miners, and creating other obligations, and in the end have no funds to pay them. If miners and business men of other camps would maintain a like front toward corrupt schemes and companies, honest investors would receive great encouragement.

Some excitement and no little scandal has been occasioned in mining circles here by the recent change of

Management of the Robinson

Mine, the outgoing manager being accused of some decidedly disreputable actions in connection with his management of that property. It is alleged that he leased an adjoining mine and connected it with one of the richest ore bodies in the Robinson by a tunnel, through which he extracted a large amount of high-grade ore. Also, that he sent a great many car loads of ore to the smelter in his own name, and appropriated the returns to his own use. It is to be hoped that he can disprove these charges, as such occurrences, coming to the knowledge of capitalists, work an inestimable injury to legitimate mining.

Messrs. Geo. M. Miller and Felix McLaughlin, extensive mine operators of Park Co., returned yesterday from a tour of inspection through New Mexico. They do not think very highly of that country, and say that Colorado offers better inducements for investment than New Mexico.

C. F. BLACKLEDGE.

Denver, Col., Jan. 21, 1883.

ELECTRICITY ON TAP.—Prof. Brush, President of the electric light company bearing his name, has succeeded, it is claimed, in perfecting a system for storing electric power. The invention consists of a box containing cells, in each of which is suspended two lead plates electrically treated and immersed in acidulated water. These plates are called accumulators, on which is stored electricity. The batteries can be packed and shipped as merchandise, and handled without danger. The capacity of the battery depends upon the number of cells. The electricity loses none of its force from storage, and can be used for any purpose for which it is needed.

The Floridas.

The Florida mountains, that on a bright day can be seen for miles from the plain on which Denning, New Mexico, is situated, formed for many years a safe retreat for the bloodthirsty Apache, and were shunned by all prospectors, are at last upon the eve of an era of prosperity, and their hidden treasures are being torn from their bowels by the miner. Although there are no well-developed mines in these mountains, the ore that is now being produced is of an excellent character, and from the size of the veins, the district bids fair to take a front rank as a bullion producer when smelting works are established at some adjoining camp, and more capital can be attracted to work the many promising claims. The ore is similar in character to that found at Cook's Peak, and is mostly composed of carbonate of lead, carrying silver. It is soft and easily worked. As an example of this, it is said that three men were able to mine and hoist nine tons of ore from a mine in 12 hours, a most remarkable feat. The Silver Cave mine, recently bought by J. E. Carroll & Co. for \$25,000, is an excellent piece of property. It is situated about 28 miles from Denning, by the road that winds around the mountain and passes through the pass between the Little and the Big Floridas. Five hundred tons of ore from this mine shipped to the Shakspeare smelter for reduction gave very satisfactory results, running from \$50 to \$68 per ton in silver and from 50 to 60% in lead. The vein that has been dipping constantly into the mountain side now descends almost perpendicularly, and at the bottom of the shaft is five feet wide. Assessment work has been done on several other mines in this vicinity, and most of the claims are looking well.

Horton's camp, situated on the west end of the main range of the Floridas, is about 12 miles from Denning by road, and contains some of the best prospects in that section. On the Carbonate cave mine thirty-five feet have been sunk and very good mineral is being produced, specimens of which assayed 200 ounces in silver and 50% in lead. The vein is a large one, probably 10 or 12 ft. wide, no foot walls having as yet been found.

The Black Bear at a depth of 20 ft. shows a vein 8 to 10 ft. wide of ore running from \$40 to \$75 silver and from 35 to 40% lead. Mr. Horton has done the assessment work on 10 other claims, all of which contain rich ore of the same description as the above.

Messrs. Shaw, Arnold and Ensign own five claims at Mineral Cave, between Horton's and Cedar springs, where excellent water is found full of gravel and supposed to have run dry, but when its basin was scooped out, it ran full to the edge once more.

The Mountain Boy, the most developed mine as yet, at Mineral cave, is but 12 ft. in depth, but carries ore running 33 ounces in silver. The vein, which was but 18 inches wide on the surface, is four feet in the bottom, and is becoming richer as it goes down. The walls are well defined, being granite on one side and porphyry on the other. The southwest extension of the Mountain Boy at a depth of five feet contains a good vein running 28 ounces in silver. The other three locations have not yet been worked, but good walls are seen on the surface of each one, and the surface rock assays from 10 to 30 ounces of silver. Wood and water are found in the mountains in sufficient quantities for camping purposes, but there is not enough of either to run mills.—*New South-west.*

The Shakspeare Smelter.

The smelter, which was completed in February, 1882, was erected by the Shakspeare Consolidated Smelting Company. It was bought by A. M. Gmelting, H. W. Schmidt and the Carroll brothers, George L. and J. E., some four months since. About \$18,000 were invested in the erection of the works. It commenced running in February, and in three weeks turned out two car loads of bullion which averaged 500½ ounces of silver and 8½ ounces of gold to the ton. The ores treated were from the Victoria and Last Chance mines. The second run was in June—ten days—resulting in one car load of bullion which yielded 465 ounces of silver and 8½ ounces of gold to the ton, from the same mines.

The third run was made in November—fifteen days—producing four car loads of bullion (60 tons) averaging 250 ounces of silver and one-half ounce of gold. The ore for this run was from the Floridas and Last Chance.

The fourth run was made in December, just previous to our visit—eight days—upon copper ore from the Superior mine. The result was fifteen tons of 97 per cent. copper, 100 ounces of silver and 3 ounces of gold, a total value of \$450 a ton, together with four tons of copper mat assaying 81 per cent., worth \$243 per ton.

At the time of our visit the smelter was ready to start the next day with quite a quantity of Superior copper on hand, and 600 tons of galena ore, which would yield from 30 to 40 ounces per ton.

The difficulty they have had to contend with is lack of ore. With millions of tons within 10 miles of them, it is difficult to obtain the comparatively small quantity necessary to keep the smelter running. Those who are getting it out in any quantity are proposing to erect their own reduction works and have no ore to sell.—*Lake Valley Herald.*

Making White Lead.

The New Germania Works, Near Salt Lake.

At the Germania smelting and refining works, south of this city, says the Salt Lake *Tribune*, work goes on day and night without interruption, and a constant stream of metal is pouring from its furnaces. The plant extends over a large surface, and there are all the conveniences of railroad tracks for bringing in supplies. Two stacks are run at a time, while two others remain idle, thus giving an opportunity for repairs. It requires from 80 to 90 tons of ore and fluxing materials to feed the furnaces, while coke and charcoal make up 12 or 14 tons more. The quantity of coke is two or three to one of charcoal. It takes from two to three car loads of lime rock and about the same amount of iron ore per day. The lead and silver ores come from Bingham, Alta, Park City and other places in Utah, Nevada and Idaho. About the works there are employed about 80 men.

In the earlier days of the Germania, it was their custom to send the product of the smelters to market in the form of base bullion. This was found to be less profitable to the company than it would be to separate the precious metals from the lead. The refining department has been successful in producing fine bullion, and establishing for the works a reputation for the quality of its refined lead, said to be chemically pure. This lead has commanded a ready market for the manufacture of shot, white lead, and for shipment to China and Japan for use in the arts there. The entire smelting and refining works appear to be under excellent management, and operated so as to save all the metal possible in the process of reduction. All the latest improvements, such as dust collecting flues, improved machinery, etc., are found here.

For several months past the company have been engaged in perfecting their plans, erecting buildings, purchasing machinery, and getting everything in readiness for the new

White Lead Works.

This is altogether a new enterprise in the Rocky mountains, there being no such works between the Missouri river and California. For this new business of the company a building 75x125 ft., and two stories high, was erected, having solid brick walls and very strong framework for the floors and roof. At the south end of this large building is another 75x40 ft., one-story high, in which is placed the motive power on one side and machinery on the other.

The New System.

Under the old system of manufacturing white lead, it required from four to six months to reduce thin sheets of lead placed in acids to white lead through oxidation; but the new process adopted by the Germania Co. does this in from 15 to 20 days, and produces a better article than under the old plan. The mode of manufacture does not appear complicated, and yet it is a very interesting process. Refined lead is taken into the factory in bars weighing nearly 100 lbs. These are cut for convenience in handling and for expedition in melting, after which the pieces are fed into a kettle and melted. On one side of this kettle a number of small tubes project downward at an angle of about 45°, and having a small stamp at the lower end. Similar tubes connected with a steam pipe and placed slightly inclined upwards have their point of discharge almost in contact with the upper pipes. As the lead in a molten state passes out of the pipes in a fine stream, it is blown by a jet of steam into a large room prepared for the purpose. The lead thus treated falls to the floor in the form of minute granules, after which it is taken to the second floor by means of an elevator. On this floor there are 21 revolving cylinders, made of wood and heavily ironed. These are in size five feet in diameter and ten feet long, inside measurement. They have two iron girdles around them for the purpose of support, and, resting on wheels, the cylinders are caused to revolve similar to those used for drying and roasting ores.

At each end a pipe enters for the purpose of conducting currents of carbonic acid gas, and there is provision made for filling and unloading them. When in operation three tons of prepared lead will be placed in each of these cylinders, with proper proportions of acetic acid and water, and then the cylinders will be put in motion. Carbonic acid gas is collected from the spent gases of the boiler furnace, and passed through the cylinders while still warm, causing rapid oxidation. After this process has gone on a sufficient length of time, the charge will be taken out and run to large tanks below, there to be agitated and washed, after which the mixture will be permitted to settle. Such particles as have not been thoroughly converted into the pigment desired will sink to the bottom and be covered with pure white lead, after which the water on top can be drawn off.

When this white lead is dried, the next process will be that of mixing with oil and grinding ready for use, then placing in kegs for market. The capacity of the works is about five tons per day.

By the side of the building lies 60 or 70 barrels of linseed oil, said to be about one month's supply for the works.

The Motive Power

Consists of ample boiler power, and an engine of 80-horse power. In one corner of the building there stands a furnace for melting lead to be converted into pipe. By its side is a large hydraulic press, provided with reservoirs for hoisting molten lead, dies for various sizes of pipe, and all conveniences for forcing lead from the press in the form of pipe of any length or

size desired. This branch of manufacture will be put in operation after the white lead department is fully at work. There is also machinery for making sheet lead. The works will run day and night after starting, which will be within the next two or three days, and be lighted by eighteen electric lamps operated by a Brush machine.

The building is heated by steam pipes extending around the walls. Everything connected with the construction of the building, the machinery, and all its arrangements, is first-class, and especially designed for convenience and economy in operating. It will require a force of about twenty men to run the works, but at the present time there are more than double that number engaged. This new enterprise is destined to become one of the great industries of Utah, and will be the means of introducing the growth of flax and manufacture of linseed oil here, besides aiding in other industries.

About Wood.

Money in All the Timber.

Year by year the primeval forests of America are passing away. Already in many places timber and lumber are becoming scarce articles. In years past there has been great if not wanton waste of timber trees. In not a few sections people are planting forest trees, for the time is not distant when they will be needed. In felling the trees of our forest it should be the study of our people to waste no part of them. There are ways in which every part of almost every kind of tree can be utilized, and with the assistance of capital this can undoubtedly be done.

Near the town of Alta, across the Sierras, in California, they have started works by means of which they grind up the wood of certain timber trees and manufacture paper pulp. The same thing might be done on this side of the mountains. At Carson has been started a box factory. This is a good industry and will give employment to many workmen. But there are also other industries that might be started. This of the manufacture of wood pulp is one of them. All kinds of timber can be utilized in this industry. We do not say all kinds of wood will make first-class paper, but it can all be worked up into some useful article.

Not only is wood pulp made into paper, but it is also molded into barrels, casks, pails, bowls and all kinds of woodenware. In the East they are already making boxes, fancy and plain, cornices, picture frames and hundreds of small articles out of wood pulp. White woods, that have a long fiber, are used for the best kinds of paper; but almost every kind of wood can be ground up and put to use in making boxes, barrels and the like.

Only the non-resinous woods are adaptable for white paper, while the resinous woods serve well for colored paper, and for all kinds of woodenware. Thus these woods might be utilized for making boxes for berries, fruits and for many other uses.

When our people first began in the business of manufacturing wood pulp they used poplar, and for a time it was thought that only that wood, basswood, buckeye and a few similar kinds of wood could be ground into a proper pulp.

Now, however, machines have been built which turn out pulp with equal facility from all kinds of wood, different stones being required for different woods, however. The longest fiber is made from willow, basswood and poplar ranking next, respectively, in that regard. Cedar, fir and hemlock are said to work about alike, the latter working a little more freely. Maple has a fiber shorter than that of either spruce or pine, and is quite hard to grind. Birch is very hard and grinds very short. Poplar and buckeye pulps remain white for a considerable time, other woods changing color. Birch becomes pink, maple turns purple and basswood takes on a reddish hue. It is estimated that over 200 tons of wood pulp are now daily turned out in the United States.

The water power in our mountains might be utilized for grinding up such parts of the forest trees as cannot be profitably made into lumber. In this way the large branches and every part of a tree except the knots might be worked up into pulp and made into barrels, fruit and berry boxes, cornices and the like. No doubt the owners of the pulp mill at Alta will presently drift into this line as a means of profitably disposing of such pulp as will not make a good article of paper. Out of wood pulp may be made all such articles as are manufactured of *papier mache*; indeed it is the same thing. In molding articles it is only necessary to mix the pulp with size, glue, cement and other similar adhesive articles or preparations, owing to what use the thing manufactured is to be put to.—*Virginia Enterprise.*

THE Nevada Legislature has been wrestling with a bill intended to abolish the use of seals to legal documents. It is claimed that such things are out of date and of no earthly use.

THE proposed transfer of the Signal Service to the Interior Department is opposed by General Hansen, but favored by most of the observers.

A FOUR years' gas war in Los Angeles has been ended by an order of the City Council to the gas company to shut off all street lights, the electric light having been substituted.

MECHANICAL PROGRESS.

Steam Heating.

The recent railroad disaster at Tehachapi has attracted much attention among the mechanics to the practicality of a more extensive introduction of devices of heating by steam. In this connection it may be remarked that the city of Denver, in Colorado, has perhaps made more practical progress in this direction than any other city in the world. At least it is said that out of 27 steam heating works in the various cities of the United States, those at Denver are the only ones that have yet returned any dividends to the stockholders. These works are operated by a capital of \$150,000, mostly owned by Denver parties. The works consume 80 tons of coal per day. They consist of 15 horizontal, tubular boilers, 5x17 ft., and are enclosed in a brick building of two stories, neatly and substantially constructed. These boilers evaporate 10,000 gallons of water per day, which heat 40,000 square ft. of piping. There are laid in the streets about three miles of main pipe—from three to eight inches in diameter—and about one and a half miles of service pipe. Eight large blocks of buildings and several private residences are heated by these works. The works have enlarged during the past year by the addition of three boilers and about one-half mile of piping. Their success is one of the best evidences of Denver's prosperity, as well as of the enterprise of her citizens. The fact may be attributed not least to the liberality of Denver's citizens than to the ability, care and intelligence with which the works have been managed by the present Superintendent, Mr. William Ridley.

TO MELT BABBIT METAL.—Workmen who are accustomed to mixing or treating metals while in liquid state, will generally melt such metal upon a blacksmith's forge by applying heat so rapidly that the ladle will become red hot before the metal within begins to melt. When it is melted a dross rises to the surface, and it is skimmed off by the workmen and thrown away. The skimming process is kept up as long as the ladle is kept on the fire. Now, such a course is all wrong, because, by applying heat too suddenly, the metals which fuse at lower degrees of heat sweat out, and are burned before those which melt at a higher temperature become fluid. The dross, as it is commonly called, which rises to the surface, is in many cases the antimony, or hardening property of the alloy, and should not be thrown away. The surface of the melted metal should be kept covered with fine charcoal, which will prevent oxidation. A small lump of sal ammoniac should also be kept upon the surface of the metal. The metal should always be stirred before pouring, otherwise the heavier metals will separate and sink to the bottom of the ladle, and a constantly varying quality of metal will be the result. By melting the metal slowly and keeping it properly fluxed as described, it will run sharp, each casting will be uniform throughout, and the metal be of equal hardness. In observing these simple precautions, much of the dissatisfaction now experienced in using Babbitt and other anti-friction metals will disappear, and the metal not be condemned because it simply obeys the laws of nature and separates when improperly treated. —*Cotton, Wool and Iron.*

RESULTS OBTAINED IN PRACTICE.—The best automatic non-condensing engines furnish an indicated horse power for about three pounds of good coal, depending somewhat upon the fitness of the engine for the work and the quality of the coal. With a condenser attached a consumption as low as two pounds has been reported, but this is an exceptional result; two and a half pounds may be quoted as a good practice. The larger the engine the better the showing as compared with smaller engines. For ordinary slide valve engines the coal burned per indicated horse-power will vary from 9 to 12 lbs.; for the sake of illustration we will say 10 lbs., and that the engine is of such size as would require for a year's run \$3,000 worth of coal; now an ordinary adjustable cut-off engine with throttling governor ought to save at least half that amount of coal, or say \$1,500 per year; if the best automatic engine were employed, using two and a half pounds of coal per horse-power, a further saving of \$750 per year could be effected, or between the two extremes, \$2,250 per year in saving of coal without interfering in any way with the power, with the exception perhaps that the automatic engine will furnish a better power than the former engine. It is easy to see that it is true economy to buy the best engine and pay the extra cost of construction if the saving of fuel is an element entering into the question of selection.

OILING MACHINERY.—A great difficulty with all types in the use of machinery is the wasting of oil by its too profuse use. It often happens that a bearing will heat when supplied with too much oil that will run cool when supplied with the proper quantity. The reason is that when the lubricator is partly worn it becomes sticky; it resists removal; it remains tenaciously between the shaft and its bearings; whereas, too much of it, usually thin and limpid, serves to "wash the bearing," and let the parts into closer contact.

AMERICAN rail production in 1882 is estimated by Mr. James M. Swank, Secretary of the American Iron and Steel Association, to have been about 1,750,000 tons of 2,240 lbs. The production of steel rails he gives as about 1,500,000, against 1,210,284 tons in 1881, and of iron rails 250,000 tons, against 436,233 in 1881. In the latter part of the year scarcely any iron rails were rolled, the prices accepted for steel being probably less than the cost of manufacturing iron rails. The imports of rails during the year were probably just about 200,000 tons, so that we have a total of 1,950,000 tons provided for a year's consumption. This is about 10,000 tons more than last year, whereas we constructed at least 2,000 miles more of new road, which would require probably 200,000 tons of rails. But the consumption for second tracks, sidings and renewals this year was very likely less than in 1881. Though there was a great deal more road to maintain, a very large proportion of it was new, and most roads had been put into condition to carry more traffic than they could get to carry last year. The great increase in the capacity of the Bessemer works made in 1881 seems to have resulted in an increase of nearly 25% in their production, which was enough to lay 17,945 miles of track with 56-lbs. rails. This, by the way, can no longer be regarded as the standard American weight. Most of the old roads with heavy traffic use heavier rails for renewals, at least on their main lines, and several of the new roads also.

THE POWER REQUIRED TO SHEAR HOT STEEL BLOOMS.—Writing to *Stahl und Eisen*, Mr. R. Lauenstein, assistant chief engineer of the North Chicago Rolling Mill Co., gives calculations of the power required to shear hot steel blooms to length for a 30-ft. rail. The shear at the works named is driven by a 10x16 horizontal engine geared one to four and a half, the stroke of the shears being nine inches and the dimensions of the blooms six and three-fourths inches square. When the engine was running at a speed of 45 revolutions, the power is just sufficient to cut the blooms, the speed of the fly-wheel being sensibly affected. When the blooms were not quite hot enough, the engine stopped without entirely cutting through the bloom. This, therefore, proved to be the minimum limit of speed. From this Mr. Lauenstein calculates that the entire pressure upon the cutting tool of the shears was 125,120 lbs., or 2,746 lbs. per square inch of the bloom to be cut.

FIRE RESISTING WOODEN FLOORING.—Among the various plans now resorted to by English builders for rendering wooden flooring resistive to the action of fire, is that of constructing solid timber floors, composed of ordinary joists placed close to each other, and spiked or screwed at intervals with bolts; the latter are fixed alternately, and to form a key for the plastering angular grooves are cut under each joist, these grooves forming a series of dovetails. In a similar manner stairs are formed by a series of joists screwed or spiked together. With regard to partitions, preference is given by many to the French plan of constructing them with quarterings, filled in with rough stone rubble, then laid on each side with strong laths, and a coat of plaster applied and pressed through the vacuities from each side. In the construction of roofs the laying of solid concrete flat on iron joists, or iron joists fixed to the inclination of the roof, and then filled in with concrete on the French system, covered with asphalt, is a method highly approved. American builders may find these modes of construction worthy of imitation.

BENDING TUBES.—The common practice in bending copper tubes is to fill them with lead or resin, then bend them round a chuck, or something of the same radius as that required for the bend. The lead or resin may then be melted out. A machinist of Philadelphia some years ago devised an ingenious apparatus for this purpose, which, however, has not come into general use. It consists of a flexible mandrel of steel, made of wire of square cross-section, and with the coils lying in contact so as to form a close spiral. By inserting one of these of the right diameter into the tube, it can be bent to any angle without showing the slightest symptom of wrinkling; when properly bent the mandrel can be withdrawn by taking hold of one end of it and drawing on it, giving it at the same time a slight twist to lessen its diameter.

FINISHING SAWS.—A late improvement consists in tempering and straightening the saws at one operation. This is done by heating the saws to the proper degree, and then pressing them with a sudden and powerful stroke between two surfaces of cold iron. A drop press is employed for the purpose. The mechanism is quite simple and inexpensive. Its use is said to effect an important economy in the manufacture of nearly all kinds of saws, and improve their quality.

INCREASING THE STRENGTH OF IRON.—Two processes have been recently introduced by M. Sequin, of Paris, by which it is claimed that the resistance of iron to the various strains to which it is subjected is considerably increased. In one process the piece of iron is raised to a cherry-red heat and dipped in a mixture of sulphuric acid and water. In the other process the piece is similarly heated, and quenched in a mixture of one part of turpentine and six parts of water.

SCIENTIFIC PROGRESS.

Important Modifications in Electric Lighting.

If we may believe the reports which reach us on good authority, we are on the eve of important modifications in the system of general electric lighting. One invention, of which we have seen a full description, says the *Mechanical World*, makes it possible to avoid the use of expensive mains as conductors for the current by the adoption of a very simple arrangement. It may even avoid the necessity of using street mains altogether in some cases, and in all cases will render the means of distribution of current more certain and far less expensive than gas. We shall be able to give our readers the earliest full description of the new system. We have information of developments more surprising still which are now in process of elaboration, of which we are not yet at liberty to speak. Evidence sufficient is before us to warrant the supposition that that the cost of electric current will, within the next few months, be still further reduced, and that to so considerable an extent as to make it generally available as a source of power.

The *World* also states that as an instance of what may be done in regard to continuous electric lighting, it is worthy of note that recently the Edison Electric Lighting Company maintained the lamps on their Holborn Viaduct installation in constant glow from three o'clock on the previous Saturday afternoon until eight o'clock on Tuesday morning. The current is supplied by two large dynamos, driven alternately, the current being switched from one to the other five times during the prolonged run. There is no reason whatever, if the necessity should arise, to prevent the supply of current being continuous over an indefinite time, but this is the first occasion on which it has been required.

RAPID PURIFICATION OF SEWAGE.—A device which is said will solve the sewage question, has been devised and recently described in the *Chemical News*. It is closed with a water joint, and is said to be inodorous, and to render infection impossible. It is called a "Vidangense." "By a mysterious operation, which reveals a totally new principle, it transforms all the solid and liquid excreta which it receives, in a short time, and without the addition of any chemical agents, into a homogeneous liquid, scarcely turbid or colored, and almost inodorous, holding everything in suspension in the state of filaments or granules, almost invisible." The effluent which contains all the elements of the excreta, organic or inorganic, may be used for irrigation. Experiments made with a "vidangense" with glass slides are said to have proved that fecal matters introduced along with urine, soap suds, etc., are completely reduced at the end of 25 days (?). Light substances, such as paper, after having floated for a certain time, finally disappear and are dissolved in the liquid mass. A bladder adapted by means of a tube above the experimental vidangense does not swell out, but shrinks, showing that instead of liberation of gases there is absorption. All this is effected "without having recourse to any new agent or any strange force, but by the simple fact that the pan closed and filled with water brings into play a force of nature hitherto unforeseen and overlooked."

APOTROPIN.—Resci has obtained a new alkaloid from atropin, by heating so carefully with nitric acid that no nitrous acid vapors are given off, then rendering the solution alkaline with ammonia and extracting with chloroform. It contains one molecule water less than atropin, is difficultly soluble in water, easily so in alcohol, chloroform, carbon bisulphide, benzol, and amyl alcohol. Is distinguished from atropin by giving with an ammonia a violet color changing to a reddish brown. It has no effect on the pupils, but hypodermic injections produce slower action of the heart, and if taken internally in small doses, characteristic convulsions result, the symptoms of which, however, soon pass off. —*Arch. Pharm.*

NEW GREEN COLOR.—According to Ad. Carnot, a non-poisonous and permanent new green color may be prepared as follows: A solution of bichromate of potash is mixed with a sufficient amount of phosphate of soda; sodium acetate and sodium thiosulphate are added, and the slightly acidified mixture is boiled for an hour. A fine green precipitate is thrown down, which is not volatile, and is perfectly fast against air, light, dilute acids, soap, etc. It may be used for painting, calico printing, etc. For dyeing, the material to be dyed is treated with a mixture of bichromate, phosphate, and acetate of soda, and is then boiled in a slightly acidulated bath of thiosulphate of soda.

SEWAGE GAS ON METALS.—It has not been supposed that sewerage gas could exert any corroding influence on metals, yet investigations show that holes are actually worn in lead and zinc pipes by such gases. From all that appears, the gas which proceeds from the drain is the most dangerous element—exhalations of this character exercising their deadly influence both by perforating the pipes which contain them and then issuing through these apertures to mingle with the respired air. Substantial iron pipes, well ventilated and joined in the most perfect manner possible, are considered the best protection.

Something Novel in Ballooning.

New light has been thrown on the construction and management of balloons by an experiment this week which shows the way how an important change in aerial navigation may be effected. Hitherto it has been considered that gas only is suitable for their inflation, for the old-fashioned fire balloon, which acquired its ascending power by the rarefied air produced by a furnace of burning straw at the neck or lower part of the balloon, was too dangerous for practical purposes. If a balloon could be constructed of some nonflammable material, all the difficulties of ascent by means of rarefied air would be overcome, and balloon ascents, whether for scientific or warlike purposes, would be practically useful. Asbestos it seems is the substance that may be made available for the purpose, for experiments which took place last Tuesday at Hendon proved that it is the material to be used.

A balloon had been constructed, the whole of the lower part of which is of very fine asbestos cloth, while the other portion, which is of canvas, is covered with a fire-proof solution. The balloon is of a cylindrical shape, having a deep zone at the equator, its holding capacity being about 3,000 ft. Attached to the neck is a copper spirit lamp. Before inflation the balloon, which hangs like a limp rag, was suspended by a line supported by two poles or uprights. The spirit having been ignited, the inflation at once commenced, and the rapidity with which it was concluded excited the surprise and admiration of all present. Everyone knows that the inflation of an ordinary balloon with gas, even with every facility for filling it, is a work of several hours. In the present case the balloon, which, though only a model, is very nearly as large as an ordinary one, standing some 30 ft., was completely distended within five minutes, at the end of which time it was ready to ascend. This is an advantage which cannot be overrated, but it is not the only one.

The difference in expense between the gas required in the one instance and the spirit in the other is very considerable indeed, while the impossibility of carrying about sufficient gas as compared with the facility for taking everywhere as much spirit as may be required for an endless number of ascents, must strike the minds of those who desire to make ballooning a practical science. The greatest value, however, which the new balloon possesses is that it may be easily carried about by an army operating in the field, and sent up aloft at a minute's notice, so to say—an advantage which will be fully appreciated by commanders of armies. —*Iron (London), December 24th.*

Impurities in Copper.

Much difficulty was recently experienced by a New York refinery in its attempts to refine a quantity of Colorado copper. The refiners pronounced it as so full of arsenic antimony that their furnaces were, as they said, "poisoned," and rendered unfit for refining. Samples of this copper were subsequently carefully examined, but merely traces of arsenic antimony were found, not enough to produce the deleterious effect noticed. Other samples were more carefully analyzed, when the impurity was found to be tellurium, a substance not heretofore found in copper anywhere. The amount of tellurium found was very small—in the matte .12; in black copper, .097; in refined copper, .083%. It is somewhat uncertain whether the tellurium was derived from the ores of the copper or from the ores of gold, silver, lead, etc., which accompany the copper. Tellurium, it is well known, is becoming more and more generally found all through Colorado, and associated with almost every variety of ore. The effects of even a very small fraction of a single percent in the refined copper is found to be very deleterious, causing cracks in the process of rolling. The assayer to whom the examination was entrusted says in his report: "This is the first time, so far as I know, that the presence of tellurium has been detected in commercial copper. But very little of it is removed in the treatment, as the four analyses show. It is surprising how very small a quantity renders the copper red-short, and consequently worthless for rolling."

PHOTOGRAPHIC COLOR PRINTING.—M. Albert's process for rendering natural colors in a picture, by means of a peculiarly constructed photographic steam press, has attracted much attention in Vienna, the principle consisting in the analysis of the white light into the three colors, yellow, blue and red, and in the recovery of the three colors ready for the press. On a plate chemically prepared so as to receive but the yellow parts of the light, and the tones of the colors of the object to be reflected, the first photograph is taken, when a negative of that plate is at once put under the press, the cylinder of which is dabbed over with yellow paint. None but the tones of the yellow colors are now seen in this impression. After that the object is photographed on the plate made to reflect but the blue colors; this plate now under the press reflects a blue impression, the cylinder being dabbed over with blue paint. In the same manner the tones of the red colors are provided for by means of a third plate. By printing the individual pictures of the yellow, blue and red over each other, the colors intervene in the production of the picture.

MINING SUMMARY.

COMPILED EVERY THURSDAY FROM ADVERTISEMENTS IN MINING AND SCIENTIFIC PRESS AND OTHER S. F. JOURNALS.

THE Sutter Farmer says: George Baker, a Feather river fisherman, one night last week trapped five heavers in the lake back of the old Riggs place, which is just below the Briggs orchard in this county.

Adjoining the Greeley-Blackman is the Great Western, a mine lately bonded by Capt. Treglone, and run in the interests of an English company. A tunnel is being driven into the hill, and it discloses a fine ledge. Immediately opposite the Great Western and also upon the opposite side of the creek, is the Imperial, about which so much has been said and

upon the success or failure of which greatly depends the fate of that district. There are big hopes centered in the Imperial, and all appearances in and about the mine fully justify those hopes. The 10-stamp mill has just been completed, and was built by Mr. James Oliver, late of Sierra City. It is a neat and compact arrangement and is well calculated to save gold. Silver and copper plates will be used, and at the end of them are long and deep boxes with riffles to save the sulphurets. The mill will be run by water, for which a 4-foot Collins wheel will be used. The pipe and everything is all in place and is in complete order. It was expected that the mill would start regularly to work yesterday, but the ditch was completely frozen and not a drop of water could be had at the mine. There is 160-foot pressure at the mine, which is sufficient to drive all the stamps that it will ever be necessary to put in motion at the mine. On the dump there is about 350 tons of ore awaiting the mill, and ore is being hoisted from the mine at the rate of 35 tons per 24 hours, a tub being used for that purpose. There is but little waste rock coming from the mine. It is no exaggeration when we say that the rock on the dump is as lively in appearance as any we have ever seen in this district, and if it does not yield well it will be a surprise to every one who has seen it. The shaft on the Imperial is 160 ft deep, and is sunk on an angle of about 75 degrees. The first level has been started at the bottom of the shaft, and is in a distance of 60 ft. The ledge has increased from 5 ft in thickness to that of 7 ft, and looks well—a great deal better than the most enthusiastic shareholder in the mine expected to see it look at that depth. The ledge increases in size as it is opened up in the east drift. It is estimated that, when the mine is opened, \$4 per ton will be amply enough money to mine and mill the rock. The work in the mine is ably directed by Mr. John Sowden, who has been an underground miner nearly all his life. Four men are employed underground, and can easily keep the ten stamps supplied night and day. The mill will crush about 18 tons of ore every 24 hours, and the owners are anxiously awaiting water so that they may start the mill, and see what their mine is going to be. If indications go for anything, the Imperial has a bright future.

PLUMAS.

EMERALD DISTRICT.—Greenville *Bulletin*, Jan. 27: The Lucky S. company are continuing to prospect two of their claims. On Lucky S. No. 1 they have sunk 50 ft on the ledge, and at this depth the vein is only 18 inches wide, but that is double what it is at the surface, and the increase in width continues as the depth increases. A tunnel is now being run that will strike the ledge at a depth of 130 ft, and at that point the company are confident of finding a good wide ledge. On Lucky S. No. 2 a shaft was also sunk on the ledge, and the developments there were sufficiently encouraging to induce the company to put in a tunnel similar to that on the other claim. This tunnel is now near the ledge and all the indications favor the belief that a valuable mine will be developed there.

THE RESERVOIR.—The water in the Round Valley reservoir is now getting low; the supply may not last over a week or two when of necessity all the mills depending upon it for their power would be forced to stop. This is the second season in succession diffling altogether from any within the memory of the white settlers. While heavy storms have been raging in the East week after week, not a cloud was to be seen in our skies; now there is indication of approaching storm, and any day we may have such a downpour as will set the streams booming again.

SAN BERNARDINO.

CALICO NOTES.—Calico *Print*, Jan. 26: Work has been resumed on the Cuba No. 1 mine. Four men are at work opening a cut in the west end; the showing is good. There are about 8 tons of ore on the dump. Fourteen tons have already been milled at the Pioneer mill at Howley's.

Adjoining the Cuba No. 1 is La Belle, owned by a Los Angeles company, Messrs. Freeman & Maxwell. The character of the ore in this claim is similar to that of the Cuba No. 1, and judging from present appearances it will yield as rich returns as the latter.

LAST CHANCE.—Last Tuesday Mr. F. O. Wilkinson, foreman of the three mines, La Belle, Loma de Plata and Last Chance, owned by Messrs. Freeman & Maxwell, called at our office, and from him we gain the following information: There are 9 men at work on the 3 above mentioned claims, most of them working on the Last Chance. This mine continues to show up fine. A tunnel has been run in 60 ft, a crosscut 20 ft, and they are about ready to sink a perpendicular shaft on the ledge. A large quantity of ore was taken to Sherman's mill, which returned \$99 to the ton. It is the intention of Messrs. Freeman & Maxwell to put up a 10-stamp mill in about a month, as they are satisfied their mines will amply pay them to do so. Mr. Wilkinson went to Los Angeles last Thursday to see about matters relating to the mill project. When he returns he will ship several tons of average ore to San Francisco to test its value.

BLACKFOOT.—Vinton L. Mitchell has bought a two-third interest in the promising claim, Messrs. Taggart & Sinclair owning the remaining one-third. Five men are at work taking out from 6 to 8 sacks of fine ore daily. Some ore was shipped to the Pioneer mill last week, and the returns from the same were good.

SILVER ODESSA.—The lumber for the chute to be erected at this mine is on the ground, and the work of constructing the same will be commenced in a few days. There is a force of 7 men under the employ of the company engaged in finishing the grading of the road that leads up the canyon to the mine. When that work is completed the men will be put to work on the mine.

SILVER KING.—We paid a visit to the office of Messrs. Johnson & Markham, who have leased the Silver King, for the purpose of learning the progress of the mine. From what we could learn from Mr. Barber we can say that the mine is doing very well. Ten tons of ore that averages well is being taken out daily, and after the necessary preparations twice that quantity will be taken out in a few weeks. The company are about to let the contract for hauling the ore to the Oro Grande mill. There are five levels opened in the mine. The first is called the west end level and is 92 ft from the apex of the vein. From this level to the next lower one, the winze level, it is 95 ft, thence to the next below, the upper tunnel level, 50 ft, thence to the east end level 55 ft, and

92 ft from thence to the lower tunnel level. The distance from the apex of the vein to the floor of the lower level is 375 ft. Five tunnels and two drifts have been cut into the mountains. The west end tunnel is in 141 ft, the east end 67 ft, south branch of east end 18 ft, winze level 65 ft, lower 172 ft. The upper tunnel west drift is in 150 ft from the main tunnel, and the upper tunnel east drift is 92 ft from main tunnel. There are several winzes and a perpendicular shaft of about 90 ft. There are two substantial shutters for conveying the ore to the large bin below, and a force of men will be put on in a few days to finish the road so that it will be easier hauling ore for the same. Two shops are kept busy sharpening tools and repairing machinery.

BISMARCK.—This mine continues to show up fine. There are 6 men at work on the same, taking out about 8 sacks a day of ore that assays high. It is transported to the wagon road on burros. Forty tons of ore have been taken to the Oro Grande mill, and another shipment is about ready for the mill.

SIERRA.

GOOD GRAVEL.—*Mountain Messenger*, Jan. 27: Mr. Gilligan, of the City of Six, has at last found good gravel in his claim at that place. He has been running west, under the large flat, where no prospecting has ever been done before, and the gravel he has struck looks and prospects well, and there are indications of a large body of it ahead. W. L. Campbell has been up at the Black Jack mine doing the annual work upon the claim. He reports that he has discovered the ledge in the lower tunnel. We always believed the property was valuable, but that it had not been properly managed. The Blue Gravel mine, above Sierra City, is showing good indications. The tunnel is now in broken material, and they are confident of striking gravel soon.

Nevada.

WASHOE DISTRICT.

SIERRA NEVADA.—*Enterprise*, Jan. 27: The east crosscut on the 2700 level is still following the east and west quartz deposit or "cross-course," and it is expected that in a few days it will encounter a vein running north and south, as it is doubtless a cross-fissure between two north and south fissures. At its intersection with a north and south vein a considerable amount of quartz will doubtless be found, and probably some ore.

HALE AND NORCROSS.—The drift north on the 2600 level joint with Savage has reached a vein porphyry which contains streaks of excellent ore, the assays running over \$100. According to the best information obtainable one of these streaks has a width of 15 inches. The indications are that these strong seams of ore are the feeders of an ore body of value, one side or the other of the drift. The point where this ore has been found is near the middle of the Hale and Norcross ground.

UNION CON.—The joint Mexican east crosscut on the 2900 level is beginning to show a good deal of quartz, and this quartz is now yielding low assays. The quartz appears to be increasing in quantity and improving in quality in going eastward.

OPHIR.—The station at the 3100 level of the joint Mexican winze will be completed this week, and next week an east crosscut will be started. The station is being cut out in the porphyry horse, which consists of the same material at this point as was shown where it was cut through by the winze. In a few days mining men will be closely watching the work at this point—the deepest mining on the American continent.

MEXICAN.—Excellent progress is making in cutting out the station at the 3100 level of the joint Ophir shaft. The station will be finished this week, and next week a crosscut will be started eastward across the vein.

SAVAGE.—The north drift joint with Hale and Norcross, on the 2600 level, is making good progress. It is now about the middle of the Hale and Norcross ground, and is in material containing streaks of ore of excellent quality, seemingly indicating that there is in the vicinity an ore body of importance, of which these ore seams are the feeders. The assays run up to over \$100.

POTOSI.—Good progress is making in the south drift on the 2600 level, and the material is such as gives promise of ore at some point ahead, or in the vein when crosscuts are run. They are now running more to the west than formerly, which takes them deeper into the vein, which appears to be swinging out to the east.

YELLOW JACKET.—The old upper levels continue to yield 60 tons and over of very fair milling ore daily. A considerable amount of prospecting work is in progress.

UNION.—Good headway is being made in the work of changing the pumps. About half (500 ft) of the new road is in position. The 1,000 ft of new road which is being put in from the surface down is 18 inches square. In about two weeks the new pumps will be in operation.

CON. VIRGINIA.—All is going on about as usual. There is no change worthy of note at any point. The water, however, is gradually draining on the 2500 level through the drift that runs out toward the Best and Belcher and Gould and Curry.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, Jan. 27: Excellent progress is being made in sinking the main winze from the fifth shaft level, the distance made during the week being 16 ft. The total depth on an incline is now 108 ft, and it is expected that a perpendicular depth of 100 ft will be reached at the close of the coming week. When this is accomplished crosscutting will be commenced. Crosscut No. 2, on the same level, is in a distance of 19 ft, and shows a formation of decomposed quartz in the face. Stopping on the fourth shaft level is now in progress, the vein showing a width of 20 inches of excellent ore. The outlook is very promising on the second intermediate shaft level. The west stop is showing 50 ft in length of ore, varying from 1 to 3 ft in width. There is no decrease either in the quality or quantity of ore in the stopes above the first shaft level, the production being as usual. The other shaft levels present about the same appearance as last week.

The usual amount of work is being done on the levels above the adit, and with very satisfactory results. The new development on the ninth level is an important one, being in ground heretofore unprospected. This body of ore has been developed a distance of 14 ft, and is now showing a vein 4 ft in width of fine grade ore. About 67 tons of ore are being extracted daily, and sent to mill No. 2, which is running smoothly and continues to do good. The shipments of bullion amounted to \$17,959.09 for the week ending on the 25th inst., the total on January account to the same date being \$56,270.

MOUNT DIABLO.—The stopes above the drift connecting winzes Nos. 1 and 2 does not show quite so well as at the date of last report. The ore in the stopes above winze No. 4 is not looking so well as last week, being narrower and more mixed with waste. It averages \$120 per ton. Some \$70 quartz is being taken from the raise near the shaft on the second level. The stopes above the west drift from the Callison winze is turning out some \$80 ore from several seams in a wide ledge.

COLUMBIA'S CON.—The raise from the east drift on the second level is now 23 ft in length. It still remains in the body of ore which it has been following, and continues to give assays of a quality as good as when first encountered. The raise from the west drift, on the first level, is now up a distance of 30 ft, and is showing 18 inches of ore, which gives average assays of \$100 per ton.

EUREKA DISTRICT.

A STRIKE.—*Sentinel*, Jan. 28: We were shown yesterday a piece of very fine rock from the Kitty tunnel. It is rich in black metal, and will probably go \$150 per ton. The tunnel, owned by Col. E. N. Robinson, is being worked by a force of 6 miners, on two 10-hour shifts. It is in 600 ft. A seam had been followed on an apraise, but the ground not looking favorable, the upraise was temporarily abandoned, and the seam was followed downward below the tunnel level. In sinking a ledge of mineralized rock was uncovered, in which a small seam from 2 to 3 inches of the ore mentioned was discovered. It is a flattering prospect.

TUSCARORA DISTRICT.

TUSCARORA TUNNEL.—*Times-Review*, Jan. 24: The ore from the Tuscarora tunnel, extracted from the west crosscut, after being very carefully assorted, and including much which should never have seen the stamps, returned \$149.50 per ton. This result is regarded as indicative of the richness of the ledge, which sooner or later will be reached. Scientific men who have examined the ground have come to the conclusion that the vein, when struck, will be a contact vein lying between the wall rocks of syenite and porphyry. The porphyry will be found on the north-west side. Numerous stringers are encountered, and a formation, as such resembling the Comstock formation as the Comstock itself, is found at the breast of the main tunnel.

NORTH BELLE ISLE.—*Times-Review*, Jan. 25: The shaft has been sunk 11 ft, making a total depth of 317 ft. No change in formation.

NAVAJO.—During the past week the shaft has been sunk 10 ft. Winze No. 2 has been sunk 18 ft, showing well at the bottom. The stopes are producing the regular quantity and grade of ore.

BELLE ISLE.—During the past week the north drift has been advanced 22 ft, and still shows seams of good ore. The winze has been sunk 27 ft, with no change in formation or general appearance.

ARGENTA.—Crosscut has reached the hanging wall. Total distance between walls 54 ft. There is a streak of good ore on the hanging wall. A drift is being run west in it, and it is improving as it is extended. The east drift on the 700 level of the Grand Prize will soon reach the Argenta ground, and when it does the work of opening up the ground between the 600 and 700 levels will be rapidly pushed ahead.

ELKO CON.—The ledge continues to show a marked improvement in the quality of ore. Assays from the ledge give a result of \$91.66 in silver and \$101.29 in gold. Total, \$192.95 per ton. The ledge is from 3 to 5 inches in width, with every indication for its widening.

GRAND PRIZE.—A winze has been started 125 ft west of the shaft below the 600 level. The ledge is strong and producing some high-grade ore. The north crosscut in the 700 level is cutting into some good quartz. Machinery all working well, and no trouble with the water.

Colorado.

RICO.—*Rocky Mountain Mining Review*, Jan. 29: The latest "rich strike" is reported from Rico. It is claimed that ore running away up into the thousands has been found in quantities. If this is true, and the ore body is a large and permanent one, a demonstration will soon follow. It will be well, however, for miners and prospectors to wait until something more authentic is heard from that section before rushing in there.

HUKILL.—*Georgetown Gazette*, Jan. 26: The Hukill company has been reorganized during the past few weeks, and steps have been taken to relieve it from its indebtedness. A competent man is to be sent out to look after the company's interests and resume work. Hukill stock has risen from 8 to 19 cents.

THE EMPIRE CITY.—This old mine (Suttle & Moore) has exposed a body of ore some 10 inches in width and about 50 ft in length. In the old drift, now in some 300 ft, the ore was meager and scattered. A raise was begun, which resulted as above. The ore mills about 5 ozs gold per ton. Six men are at work driving the drift ahead and stopping.

ORE.—A carload of ore for a test run has been shipped this week to Argo for the Upper Union Tunnel Company, by Johnson & Swanson, from the Cashier mine at Empire. The ore consists mainly of iron pyrites and surface quartz. The mill-runs of the solid ore are from 5½ to 9½ ozs gold per ton. This ore was taken out in four and one-half days by 5 men, and amounts to 5 tons.

THE VIRGINIA CITY.—At this mine, on Lincoln mountain, work has been prosecuted with activity by the leasers, Messrs. Richardson & Co., who are now in a fine body of ore. The drift has been opened up for some 130 ft, 80 of which was in ore. At the present writing they are sinking a shaft in ore, and are now 25 ft below the drift level. The ore is from 10 to 18 inches in width, and nulls 285 ozs per ton. The shaft is to be sunk 100 ft, when a drift east and west will be started.

New Mexico.

BURRO MINING DISTRICT.—*New Southwest*, Jan. 18: The Boston Syndicate are the fortunate owners of nearly 50 mining claims in this district, upon which they have had employed and are employing a large force of men doing the assessment work. In nearly every direction the mountain sides are dotted with ore dumps, which have considerably augmented within the past few weeks,

Arizona.

BISBEE.—*Cor. Tombstone Republican*, Jan. 26: The machinery for the new hoisting works of the Copper Queen has all arrived. The boilers are already in place, and the masons are walling them in. The engine, which is a 10x14 double cylinder, arrived yesterday, and will be set up as soon as possible, so as to commence sinking on the incline for the next level, which is expected to expose a bonanza of cuprite (red oxide) and native copper, as the bottom of the third level is in such ore. Another No. 10 Cameron pump has arrived, which is to be used in sinking. A tramway is being built from the road up to the hoisting works, where an engine will be placed for hoisting up timber, wood and supplies for the mine, which will be quite a saving to the company, as it was formerly hauled up the hill with animals. The work that has been done on the Mammoth has shown up well, as there is about 70 tons of good copper ore on the dumps, and more in sight.

THE COPPEROPOLIS.—This mine has temporarily shut down, but it is reported that they are going to put up a hoisting engine and pump, as they have struck water at 90 ft.

THE DELLA MACK.—This mine, with the last work, is showing fine, as they have about 2½ ft of very rich ore in the bottom.

PROSPECTING.—There is considerable prospecting being done out at Solomon Springs. Some prospectors brought in some float which assayed over \$700 in silver and 50 per cent. copper. Mr. Charles Young has a lease on the New El Dorado mine, in which there is very rich silver ore. He is to sink 50 ft and drift the same. There is ore there that assays several thousand dollars a ton. The gangue of the ore is quartz, carrying chloride and horn silver. The Copper Bullion mine is being developed, and has a good showing of carbonate of copper. Taking things in general, Bisbee is looking encouraging.

Idaho.

MORE MACHINERY FOR WOOD RIVER.—*Wood River Times*, Jan. 26: Mr. Marsh, of Galena, left today via Blackfoot for New York City. He will meet Major Stafford at Chicago. These gentlemen are interested in the mines near Galena known as the Galena group. They will immediately contract for and ship to the mines sampling works, machinery complete, and concentrators to operate with the sampling works; also pumps and hoisting gear. The machinery will come by way of the Oregon Short Line and Naples. Mr. Marsh will return to the mines in March.

THE ONTARIO ORE BODY AGAIN CUT.—The ore body of the Ontario mine, on Warm Springs creek, was again cut last week in the drift.

Montana.

PONY.—*Cor. Butte Miner*, Jan. 27: Judging from the flattering reports coming from the mines near here, Pony is soon to have a boom. She started at a lively gait, was "downed" on the turn, but is coming back on the home stretch with flying colors; so it's a kind of boomerang after all. A number of men are engaged in extracting ore from the different mines. Much of the ore is base, particularly in the Boss Tweed and Willow Creek lodes. The crevice of the former lode is 30 ft, wide while that of the latter is from 5 to 8 ft in width. The Ned has free milling ore and a 3 foot vein. One hundred thousand dollars is the estimated amount in sight in the mine, besides a large dump on hand. The ore averages \$55 per ton in gold. The White Pine is worked to a depth of 130 ft, and has now on the dump about 400 tons of \$50 rock. The dump is daily increasing. The Custer lode, a half-mile east of town, has been opened to a depth of 25 ft. It shows a fine vein 5 ft wide, with an ore body of rather low grade, but which no doubt will pay well for working. Many other good mines in the camp are being developed more or less according to the means of the owners. Henry Elling is erecting a 20-stamp mill at the upper end of town in which he intends to place concentrators, to treat the base ore, which assays well. The merchants and mechanics here are doing a good business.

Oregon.

NOTES.—*Jacksonville Times*, Jan. 26: The miners are having hard luck, as the water is very late in starting. Klipple & Keaton this week received a giant, which will be used at their claim on Poor-man's creek. Since the weather has moderated, the miners feel more encouraged and expect to make a good run yet. R. W. Derickson, of Horsehead, was in town this week. He says that some excellent quartz is being taken out there and that the mill is now operated with success. Cold weather has been the order in Josephine county as well as here. In fact it has been so cold that Wimer & Simmons' mine, which generally runs right along, was frozen up for several days. Capt. Kelly came up from Cayote creek Saturday after supplies. He informs us that he had enough water to clean up with until the cold snap put an end to operations, which were resumed this week. Dr. Reynolds informs us that he has received favorable assays from the ore he sent to Chicago. He claims that one of the richest mineral belts on the coast is located on Evans creek. Coal and petroleum also seem quite abundant.

Utah.

PARK CITY.—*Salt Lake Tribune*, Jan. 28: It is rumored that a rich vein of ore has been struck in the Washakie. Admission has been denied to all not directly connected with the mine. We were shown some very fine specimens of the ore yesterday which will assay very good. Col. Wm. M. Ferry is doing Salt Lake this week. His tunnel at the Apex mine is being extended at a rapid rate. The Apex will, no doubt, rank with the best mining properties in its vicinity, every indication going to show that there is a mine which will prove a paying one when fully developed.

Steel-Iron.

The question of producing a metal possessing the physical properties of both iron and steel has for some time past received attention at the hands of practical metallurgists and others. One of the latest workers in this direction is Professor M. Keil, who has succeeded in producing a compound metal which is stated to possess the characteristics of both metals. The Professor, in giving his experiences on the subject, states that the difficulties can be obviated only if the two materials can be intimately united into a whole. After many experiments, success has, it is claimed, at last attended them, and a material has been produced answering every requirement, and to which the name of "steel-iron" has been given. The following five descriptions have been made: (1) Steel by the side of iron; (2) steel between two layers of iron; (3) iron between two layers of steel; (4) the core of steel, the surrounding shell of iron; (5) the core of iron, the surrounding shell of steel. This steel-iron is manufactured in the following manner: A cast iron mold is divided into two parts by a thin sheet of iron securely fixed in it. The fluid steel, as well as the fluid wrought iron, which have been freed before smelting from substances preventing welding, are poured at the same time, and in the same quantity, into this doubled mold; the separating plates serving as the medium welding both parts, steel and iron, completely together, so that they form an inseparable whole. The plate serves as a separator and a welding agent at the same time. The success of the operation depends upon the quality and the thickness of the plate. The latter must be of a certain thickness, to prevent the two glowing and liquid masses burning through it; and it must not be too thick, so that they are able to bring it up to welding point while rising in the mold. The dimensions of the plates depend upon experience, and, naturally, are regulated by the dimensions of the castings. The manufacture of the above-mentioned five kinds are the same in principle. In numbers two and three, however, the mold is divided into three equal parts by two strips of plate; in numbers four and five the core is formed by a sheet iron pipe standing in the middle of the mold. It is stated by Professor Keil that the product thus obtained may be used for a great many purposes. Steel upon iron will be useful for rails, armour-plates and anvils, the hard steel face reducing wear and tear, and also, as in the case of thief-proof safes and armour plates, withstanding the attacks of even the hardest drill, while the iron prevents cracking consequent upon heavy blows. Parts of machinery and tools which are subject to powerful pressure, and are exposed at the same time to great vibration, are best made of the material with tough core and hard surface. The wear and tear would be slight, while the soft core imparts considerable strength and prevents fractures. From what has been said respecting the quality of this description of steel iron, it will be seen that the extent of its application promises to be a wide one, partly on account of its undoubted excellence, partly also on account of its many qualities, because it may be used for a great variety of manufactures.—*Iron*.

The Bonanza King Mine.

A few days since we published the gist of a telegram from Mr. Ewing, of the Bonanza King mine, at Providence, to the effect that the company had shipped \$11,000 of fine bullion for the first eight days' run. The operator in transmitting the message omitted part of it, and the fact is, that instead of \$11,000 the amount shipped was 11 bars, the value of which was \$19,000. This is the first work of the new mill, and certainly is a most encouraging starter. The Bonanza King Company have spent an immense amount of money in developing their mines, and to-day have undoubtedly the best mining property on the coast. The new mill was shipped by mule teams from Mohave station. Even while the railroad was building to the mines with a prospect of reaching them in a short time, yet they considered that the delay of a few weeks in waiting for the railroad would cost more than the extra amount for freight, large as it was, and with genuine mining enterprise hauled all their machinery over more than two hundred miles of desert, and will have saved the extra cost in a few days' run. The question of water supply was also a mooted one, but by vigorous prospecting and extensive work sufficient water has been developed to settle this question, and enough is assured both for household and mill purposes.

The Bonanza King is already the mine of our county. Its output in the short time it has been worked is very large, and the ore of high grade; immense amounts have accumulated on the dump, sufficient to insure the continuous working of the mill if it is found necessary to do any dead work, while at present more than sufficient ore is being taken out to keep the mill employed to its capacity. We are pleased to see the grit and enterprise of this company so well rewarded, and hope, for their sake and the prosperity of the county, that they may continue to ship \$20,000 in fine bullion every eight days for years to come. Nor is this extravagant when we consider what other mining property will do and is doing, and the indications are that the Bonanza King is not a whit behind the best, and that its fortunate owners may reap a rich harvest for their immense outlay of capital in its purchase and development.—*San Bernardino Times*.

Scale on Ornamental Trees.

It may interest many of our readers to know something of a pest which attacks that splendid ornamental tree, the Norfolk Island Pine (*Aracariae Excelsa*). This tree is quite a favorite for garden and park planting in this State, and its peerless symmetry is a continual joy to the beholders. During Prof. J. Henry Comstock's late visit to this coast he found a scale insect preying upon this tree, and in his report to the Department of Agriculture gives a drawing and a description of it. These we produce herewith. The insect was found on a tree in southern California. It is called the Norfolk Island pine coccus (*Eriococcus aracariae*), and was first described in the proceedings of the New Zealand Institute.

When a tree is badly infested with this pest

SCALE INSECTS ON NORFOLK ISLAND PINE AND OAK

it becomes blackened with a black fungus, which is *Fumago salicina*, which accompanies coccids on orange and other trees. This is often the first indication of the presence of the insect which is observed. But when an infested tree is carefully examined numerous white cocoon-like sacs containing the full-grown insects may be seen closely applied to the sides or bases of the leaves. Frequently these sacs are so massed at the ends of the twigs that the bases of the leaves are completely covered. The immature insects are not so easily seen with the unaided eye, as they differ but little in color from the tree. They are greenish yellow, and are usually to be found in the angles formed by the bases of the leaves. The larvae of both sexes and the adult females are similar in form (see Plate, Fig. 1d). The posterior end of the body is furnished with two prominent lobes, each terminated by a long hair. Between these lobes there is a conical mass of white waxy matter projecting backwards. The margin of the body is fringed with a row of tubular spinnerets. These spinnerets are more numerous on the adult female than on the larva. In both stages each one is covered with waxy matter, which often extends beyond the end of the spinneret. Excepting these filaments and the caudal tuft, but little excretory matter is to be seen, so that,

although the insect resembles a mealy bug in the form of its body, it differs greatly in appearance. The female, when full grown, measures .09 inch in length. When the female is ready to lay her eggs she excretes a cocoon-like covering to the body, composed of white waxy threads (Fig. 1). This sac is dense like felt, but easily torn. It is open on the middle line of the ventral surface, or very much more delicate on that part. It adheres to the tree quite firmly, remaining where excreted after the death of the insect. As the eggs are laid the body of the female shrinks away, making room for them, and finally it becomes a very small pellet in the anterior end of the sac, the remainder of the space being filled with eggs. These are light yellow in color. When the male larva is ready to undergo his metamorphoses he secretes a covering to his body resembling the sac excreted by the female, except that it is very much smaller, measuring only .05 inch in length (Fig. 1). From this sac the adult insect emerges

The Paradise Mines.

A Promising Camp.

The *Virginia Enterprise* is indebted to J. V. McCurdy, from Paradise Valley, for the following items in regard to the mines of that section:

The Live Yankee.

Which is being developed by Messrs. Nick Fryer and A. J. Shepard, of Winnemucca, has heretofore, near the surface, produced very rich ore and of a very free milling character. They are driving a tunnel to tap the ledge at much greater depth and to drain the water encountered in their shaft. The tunnel is now entering the lead, and will soon enable them to open and work the vein to advantage.

The Paradise Valley Mining Company

Have not worked their property the past two years. The vein is parallel with the Wild Goose and Live Yankee, and is a very strong and well defined ledge, and has produced many thousands of dollars in bullion. The vein crops out on the face of the mountain, and four tunnels have been driven in on the ledge from 200 feet to over 400 feet, the lowest one of which prospects the vein about 400 feet below the surface. The Paradise have a first-class dry-crushing ten-stamp mill, with White & Howell improved furnace.

The mill is about five miles from the mine on Martin creek, and is constructed to use either or both steam and water power. There is, however sufficient water to run all the machinery by changing the wheel to hydraulic pressure instead of a suction stem. At the time the Paradise people were operating, the opinion prevailed that it was absolutely necessary to roast or chloridize all their ores, and nothing under \$50 per ton would pay to handle, but by working several hundred tons of the ore from the waste dumps the past summer at the Bullion mine the wet process demonstrates that it can be worked to nearly as high a percentage as the Comstock ores.

The Wild Goose

Is a very promising property and shows a large deposit of good milling and profitable ore. The Wild Goose is owned by merchants, stock men and farmers, who have obtained the stock through business channels, and not being mining men fear (from examples set them) to risk a dollar in developing or working the mine.

The Bullion Mine.

Adjoining the Wild Goose, has been worked (or gonged) more constantly than any mine in the district; yet the deepest point penetrated is but about 200 feet below the surface, and no prospecting was done at that point. Originally the Bullion was worked through an open cut, some 20 to 60 feet deep, following the vein into the mountain. A tunnel was run from the mountain at right angles to the vein, and tapped the same about 65 feet below the upper workings. A drift was then run north in the vein some 400 feet to the Wild Goose line, showing several bunches of ore, none of which have been prospected, except one chimney about 60 feet in length, which is near the Wild Goose line. It is from three to four feet wide in the drift, but in rising up the vein has widened to about nine feet. Six feet are base in iron, sulphur and a little antimony, and the other three feet of the vein, on the hanging wall, contain quite free-milling ore, and carry chloride and native and horn silver. There is a large body of quartz in this chimney, and it carries very good ore.

In the drift at the Wild Goose line a winze has been started in the vein, and is down 38 ft. below the tunnel level and shows good ore. Eighty-six feet south of the line another winze has been started, and is down 44 ft. and is in good ore, showing that the chimney continues down 120 ft. South of the 44-foot winze a winze has been sunk 72 ft. in the vein, and a drift run north 125 ft. to connect with the 44-foot winze. Both winze and drift show a strong, well-defined vein, with bunches of excellent ore, and no doubt an extensive ore body exists in the mine at this point.

A drift was started south in the lead from where the tunnel entered the vein, and a chimney of ore found and worked out to near the surface, some of it paying as high as \$100 to the ton. This drift has been extended the past summer, and a very rich and valuable chimney of ore discovered about 60 ft. in length, and 6 to 14 ft. in width. There is a break in the vein for about 20 ft. after passing this chimney, and the drift is now showing good ore in the face.

The ores in this part of the mine are free-milling, carrying chloride, native, horn, bromide, brittle and ruby silver, and can be worked to a higher percentage than the Comstock ores.

The advantages for prospecting the Bullion and Wild Goose mines are seldom equaled. Lying parallel with a deep canyon, a tunnel of 500 to 600 ft. would tap the ledge 400 to 500 ft. below the present workings. And if some party had control of the mines that wished to make money by legitimate mining, with a little capital, proper management and energy, success would be sure. No doubt to-day Paradise presents better opportunities than many of the distant and inaccessible camps in Arizona and New Mexico.

A CHILL for chilling metal has been invented by William Tuttle, Domagiac, Mich. The chill plates being heated by the molten metal, burn the wooden core and allow the chill plates to be withdrawn.

IMPROVEMENTS IN THE FAURE ACCUMULATOR.

This device was a very crude affair when first introduced. During the past year its practical electrical capacity has been fully doubled by the various improvements which have been added to it. The Faure accumulator, as originally made, had three defects: first, that, great as was the advance it constituted on the Plante cell, still its capacity for storing electric power was not so very large; secondly, the rate at which this power could be taken out of it was limited; and lastly, some kind of flannel or felt was employed to keep the red-lead in contact with the lead plates and prevent the plates touching one another. In all these three directions the cell has been immensely improved during the last twelve months.

THE ENGINEER.

The State Engineer's Report.

The Irrigation Problem.

State Engineer William Hammond Hall submitted a report to the State Legislature concerning the work of his department during the past two years. He recapitulates the work accomplished up to January 10, 1881, a full account of which had been previously rendered in two progress reports, and complains that the appropriation of the Legislature of 1881 for his department was insufficient to carry out the wishes of the Legislature as expressed in the Act of appropriation. He had estimated the cost of completing the report on the irrigation problem of the State, and the State map then in course of preparation, and the salary list, at \$50,000, but the Legislature cut down the appropriation to \$20,000, and the entire State map was ordered completed. It will cost \$4,000, he says, to complete the irrigation report, without illustrations; with illustrations, \$1,500 additional. Other estimates are as follows: For maps compiled from the general land surveys, the last set of geographical sheets of which will be published under the auspices of the Federal War Department, \$2,500; for the completion of the general State map and atlas sheet maps of the State, \$12,000. This makes a total estimate of \$20,000, which amount he asks the Legislature to appropriate for the purposes stated.

The Engineer's Work of the Past Two Years.

The report says: During the past two years but little field work has been attempted in the line of the irrigation investigation, and that only by way of closing up unfinished work in certain localities. A more considerable item has been the collection of data for the general State maps. Within this time the State Engineer has been called upon for other duties than those relating to the main work in hand.

In the spring of 1881, at the request of the Governor and the Board of Trustees of the Yosemite valley, he made a trip to the valley, and laid out and advised concerning certain State works there to be undertaken. In the summer of 1881, under instructions from the Governor, he took charge of an investigation of the method and work of construction of the San Francisco seawall, assisted by two civil engineers, Mr. Calvin Brown, of the Mare Island Navy Yard, and Prof. Frank Soule, Jr., of the State University. This work, performed at intervals between July, 1881, and February, 1882, occupied about two months of time. The State Engineer has also been called upon, under the provisions of the law, to regulate the bridging of navigable streams in the State, to perform the duties therein specified in connection with three bridges, that over the Sacramento river at Colusa, that over the Sacramento river at Chico Landing, and that over Big river, Mendocino county, near its mouth.

The State Boundary Line.

The report calls attention to the fact of the inaccuracy of the work for fixing the State boundary lines. It appears that eastward from Lake Tahoe there is a strip of country three-quarters of a mile wide and of a length unknown, but extending many miles, which has been thrown into Nevada. The work of the Government Geographical Survey also shows that this error exists.

Another similar error is also found on the southern boundary line, between this State and Mexico. The southern boundary of the State, supposed to be a straight line or arc of a great circle, between two fixed points in latitude and longitude, according to compilations and examinations made under my direction, is not thus straight, but has in it a "jog," or offset, of about one mile at a point about midway on its course.

State Action in Irrigation.

The importance of State action on irrigation is alluded to. This work implies not only the practical improvement of the rivers themselves, as flood carrying channels, but also the regulation (not construction or maintenance) of private or district works of reclamation and land or corporate drainage, so far as these affect these streams as flood-carrying channels, and also the management of the streams and their outlets and relief escape ways, when in high flood, for their development, protection and the general good of the whole system of works and lands adjacent.

There is also, says the report, an equally wide distinction to be made between the work of keeping waters off from private lands by the building of levees—work which individuals and associations of land owners should undertake, and the improvement of public channels to carry away public flood waters—work which the State must undertake if it is ever to be accomplished. There is also a wide distinction to be made between public waters—those flowing in public streams—which should be guarded by the State, and controlled in their apportionment to claimants thereof, and waters which rise on private property, and which are generally regarded as part of that property, and subject to the control of its owner.

Again, if the public waters are to pass into the hands of corporations, or associated or individual appropriators, for use in irrigation, the transfer of right should be upon such terms as will protect the future irrigators of the State,

and the interests of the people generally who have no water rights. The present laws have no such safeguards. The report calls attention to the necessity of the establishment of a system of control and direction, which will relieve the courts of many vexatious suits, and which will inspire confidence in and add stability to irrigation property, need not constitute an attack on existing claims of right, and need not bear heavily upon or embarrass the users of public waters. The effect, under a wise system, would be felt gradually; all parties concerned would as gradually become used to it, and recognize in State control the only means of protecting the interests of each, as it has proven in every old irrigation country in the world.

A bill has already been introduced looking to legislation in this direction, which is much needed.

USEFUL INFORMATION.

False Glycerine.

Our foreign exchanges have been describing an article sold under the name of glycerine, but containing none of the real article. E. Geissler writes to the *Pharm. Centralhalle* as follows concerning it:

"Some time since an advertisement appeared in a paper in Prague, Bohemia, offering cheap glycerine for technical purposes. A firm in Dresden sent for a sample, which was duly received, but it was expressly stated that this glycerine could not be employed in food, etc. The sample was only tested physically, and as it seemed to be satisfactory, two barrels of it were ordered. After the buyer had received his glycerine one of these notices of falsified glycerine met his eye, and he resolved to test it more carefully, when he soon discovered that he had been deceived, and therefore sent the writer (Geissler) a sample for analysis.

"The pseudo glycerine was of a pale yellow color, nearly clear, and when rubbed on the hand was at first quite oily; then a peculiar dryness of the skin was noticed. The taste was very bitter and unpleasant, comparable to a very impure glycerine—specific gravity, 1.269. When evaporated on a water bath is left 53.2% of residue which looked brown, and at 221° Fahr. was quite dry and friable. When heated more highly, it puffed up and left a slightly alkaline ash. A closer examination showed that the so-called glycerine consisted of chloride of magnesium, starch-sugar (glucose), and dextrine dissolved in water. The analysis showed: Chloride of magnesium, 11.87%; sugar, 17.03%; dextrine, 35.00%. Not a trace of glycerine could be detected in it.

"The ease with which such a swindle can be detected makes it difficult to see how any manufacturer can venture to put it forth, and also goes to prove that the bolder the rogue the better his chance of success."

THE VALUE OF FOREIGN SILVER COINS.—The

Director of the Mint has authorized the publication of a statement of the valuations, in United States money, of the various coins of the world. These valuations are made by the Treasury Department on the 1st of January in each year, and govern Custom House officers in the appraisement of dutiable goods for the purpose of fixing the duties. The list of valuations is substantially the same as a year ago. The only changes are annexed:

	1882.	1883.
Austria, Florin.....	40.6	40.1
Bolivia, Boliviano.....	82.3	81.2
Ecuador, Peso.....	82.3	81.2
India, Rupee.....	39.0	38.6
Mexico, Dollar.....	89.4	88.2
Peru, Sol.....	82.3	81.2
Russia, Rouble.....	65.8	65.0
Tripoli, Mahbub.....	74.3	73.3
United States of Columbia, Peso.....	82.3	81.2

The above are all silver coins, while the valuations are in gold coin of the United States. The peso of the Argentine Republic, not valued a year ago, is now valued at 96.5, whether in gold or silver.

GREASE FROM THE CHINESE TALLOW TREE.—

The increasing rarity of tallow of animal origin has attracted the attention of candle and soap manufacturers to a vegetable grease introduced into Europe toward 1848, and the use of which is steadily growing in France and England. The tallow tree is of Chinese origin; it grows also in the northwest of India, and has been introduced into South Carolina, where it has been cultivated for ten years. It produces a fruit the core of which is covered with a layer of thick tallow, and contains a yellowish aromatic oil, used in the same country as a heating agent. After the plucking, which takes place in July in the south, and in October in the north, of China, hot water is poured on them, and the grease is skimmed off, after getting cold, with spoons; the tallow, molded into the form of bamboo canes, is directly brought into commerce. This tallow presents the appearance of a greenish mass, crystallized, having a peculiar odor. It melts at 44.3°, and becomes solid again at 40.3°.

SPIDER SILK.—There was, not long since, exhibited by Mr. Rolt, an English merchant, a thread 20,000 ft. long, spun by 22 silk spiders in less than two hours, and which was five times as fine as the thread of the silk worm,

DYEING LEATHER.—In the glove trade the leather has hitherto always been dyed by brushing on the dyes by hand. The defects of this method are its slowness, the occurrence of large, soiled edges on the fleshy side, and, notwithstanding every care being taken, the uneven character of the dye produced. To avoid these, Joseph Kristen, of Bruhl, has a process in which even dyeing is obtained by the application of centrifugal force. The skin to be dyed is fixed on the center of a horizontally rotating disk. The color is also fed on to the center, and by the rapid revolution of the disk, is spread equally over the whole surface. The color is forced on to the disk by means of a pump, or it merely flows from a reservoir standing at a higher level. The excess of color driven off at the edges of the revolving disk is collected and used over again until the skin is fully dyed. To dye skin by this method takes from 10 to 15 minutes. A single color pump may serve for at least five machines, which would require only one attendant, so that by the above arrangement one man could in 12 hours easily dye 150 skins, possessing great evenness of dye and free from spotting.

A NEW CARTRIDGE.—An entirely new departure in cartridges for guns was shown at the Seventh Regiment armory recently. The inventor claims that his cartridge will not heat the gun, that it is self-ejecting, has twice the propelling force of powder and is much cheaper. It will also, he says, cost very much less than metallic cartridges of gunpowder, and it will not be injured by water. In appearance the cartridge looks like a Chinese fire-cracker with the red paper taken off. Its materials and mode of preparation are secrets, but it looks like paper pulp soaked in some explosive material, and pressed into a hard roll. The ball is attached to the end of the roll, and the whole thing leaves the gun together, on the "sky-rocket principle." It can, he says, be adapted to any gun, and will revolutionize the ordnance departments of the world. The inventor fired one of the ball cartridges into a spruce log 8 inches thick. The ball passed entirely through the log and a 2-inch plank behind it, and flattened against a stone wall. After firing 12 rounds out of the same gun there was no apparent heat and no fouling. A more scientific and satisfactory test will be made at the State Arsenal, probably in a few days, before Government and State experts.

ENGLISH SHODDY COTTONS.—England exports annually an enormous quantity of cotton cloth, and the whole amount of the average price it is said is only 6 cents a yard. The exports to Australia average highest, 13 cents. The United States comes next, buying at an average of 11 cents. Germany and France take their portion at 8 cents, South America buys at 6½, Turkey at 6, British India at 5½, China at 4½, and the west coast of Africa takes large quantities at 2½ cents. These stuffs are the goods which the savages receive in barter. They are a flimsy fabric of loose threads strung together like mosquito netting, and the interstices filled in with a heavy sizing of clay, starch, etc., and is never intended to wash, as the first application of water nearly dissolves the fabric.

A CHEAP VARNISH.—A brilliant black it is said can be produced on iron and steel by applying with a fine hair brush a mixture of turpentine and sulphur boiled together. When the turpentine evaporates there remains on the metal a thin layer of sulphur which unites closely with the iron when heated for a time over a spirit or gas flame. This varnish protects the metal perfectly, and is quite durable.

TO HARDEN STEEL.—Take two teaspoonfuls of water, one-half teaspoonful of flour and one of salt. Heat the steel enough to coat it with the paste by immersing it in the composition, after which heat it to a cherry red and plunge it into soft water. If properly done, the steel will come out with a beautiful white surface.

GOOD HEALTH.

Treatment of Constipation in Infants.

[Written by L. U. McCANN.]

A lady correspondent asks the advice of some of "the mothers" in regard to the best treatment for her babe of ten months who suffers from obstinate constipation. The results of our experience upon this subject are heartily at her service, for we regard this as a very serious trouble to a child of that age. It is generally at this time, in the midst of its teething, which process of itself induces a feverish state in the system, and an inclination of the blood to rush to the head, when, if complicated with inactivity of the bowels, the result is often a severe congestion of the brain, or a sudden and fatal spasm, which, without warning or time even to call in the doctor's aid, snatches the little one from the mother's arms and stills forever its baby prattle in the cold embrace of death. Hence we say that a child at this age, and in-

deed, throughout the whole process of its teething, requires that the utmost care be used to keep the bowels in a state of healthy activity, as its safety at this critical time depends in a great measure upon having no obstructions of this kind to contend with.

Much may be done to prevent this trouble, if the baby is nursing, by a proper regulation of the diet and habits of the mother herself, as the state of her own bodily health will undoubtedly influence that of her child, through the quality of her milk. We have known many mothers who regulated their babies entirely upon this plan, and when necessary, by using a more laxative diet, or even by taking a mild purgative themselves, would so thoroughly affect their babies that the little ones received all their medication in this "second-hand" manner, not even required whilst nursing any other treatment for their troubles.

It is a bad plan to get into the habit of dosing children for every ache or pain, and upon all occasions. Babies are so little, and their needs in this regard are so infinitesimal, that more harm than good is apt to be done in unskillful hands, by giving them, at any time, strong medicines. When there is a real need for it, however, there should be no delay in calling in the best medical aid that can be procured, for a little child's hold upon life is a very slight one, after all, as is proved continually by the statistics of the fearful mortality among them.

Yet, with regard to the little every day ailments to which babies are heir to, we have long proceeded upon the principle that "an ounce of prevention is worth a pound of cure," and especially is this true in this matter of constipation. We believe, in all ordinary cases, the bowels can become regulated without the aid of any medicine, by having a regular time every morning, wherein the child is urged to relieve itself, when it will soon come to do so of its own accord, at that hour, as a matter of settled habit. When, from any cause, nature seemed to need a little assistance, we have found that a teaspoonful of molasses, stirred into a glass of cold water, from which the baby was given a copious drink the last thing at night and the first thing in the morning, was, if persevered in, all that was necessary as a mild aperient for the little one, soon bringing it into regular habits again, whilst the sweetened water was considered a beverage just suited to a baby's taste.

In more serious cases the quickest and surest relief (and one perfectly safe from any after ill consequences), is obtained by giving the child a simple enema, composed of water, made a little soapy, to which a teaspoon of sweet oil may be added if thought best, using about a teaspoonful of the mixture at a single time; for it is a great but common mistake to overdo this thing altogether by pumping in too large a quantity as an injection. It is much better, especially for a child, to administer only a small enema at once, leaving this to be retained as long as possible, when it will have the effect not only of softening the secretions, but of allaying the feverishness attendant upon such a disordered state of the system.

It is better that this dose should be repeated in a little while if the desired object be not attained than to administer the double dose at one time, as the retention of the solution in the system for a while seems to effect a more permanent good in this disorder.

In obstinate cases, or where, as is sometimes the fact, there seems to be a natural predisposition to costiveness at all times, it is recommended that a single syringe full of water be injected after each evacuation, and retained in the system until nature demands its expulsion.

This practice is said not only to be a sure cure of constipation in either children or adults, but also one of immense benefit to that distressing complaint known as hemorrhoids or piles, from which so many people suffer year in and year out without any relief.

The retention of this cold water allays the irritation of the parts and prevents the tumefaction of the blood vessels in this region, whose derangement from a healthy state in the first instance has generally been caused by the straining consequent to long-continued constipation. But let us return to our baby. If this child of 10 months is fed at all (and about this time these little ones like a change of diet now and then as well as the rest of us), feed it upon corn meal mush and milk or gruel, sweetened with either molasses or brown sugar. White sugar, be it remembered, has so constipating an effect that by some it is even considered as a sovereign panacea for all the summer complaints of children; so, though it is undoubtedly purer, it is best not to be used under the circumstances. Or, the baby may be given a baked apple, pared and cored, of course, and mashed soft so as to inconvenience the little one whose "grinders are few," if any, at this time, which will act as a gentle laxative and assist to overcome its trouble. Meanwhile let the mother do all in her power through the regulation of her own diet to give her milk the desired laxative quality to promote her baby's welfare. Using no stimulants of any kind, nor highly spiced or seasoned food, for herself, and taking even her tea and coffee, if she must have them, "to make milk for the baby," more than half hot water until the health of her child in this most important point is firmly established upon the basis of a regular daily habit, and in the sweet content and good nature resulting from its perfect health she will have a thousand times repaid for any sacrifices she has had to make at the table to secure so desirable an end.

Passing Events.

The little spurt in the stock market this week, and the notice it attracted, would seem to indicate that people were expecting something from the Comstock after all, and that many will not take the experience of the past, but will try their fortune again.

The anti-debris bill, giving the plaintiffs power to join miners as defendants in an action to suppress a nuisance, was killed by refusal to allow it to pass to third reading. The courts decided that the plaintiff must prove what particular mine the debris came from. By this bill they would not have to do so.

There is nothing specially new from the mining regions aside from what we note in our "Mining Summary" for the week.

The *Calistogian* says: The latest excitement in mining matters here was that occasioned by the finding of fine quartz croppings in the mountains four miles south of Windwhistle, in Sonoma county. The ledge can be traced some distance, and the quartz taken from it is really fine, and assays show it to contain from \$14 to \$692 silver to the ton, the former being the very lowest. Of course this ground has already been well covered with locations. Nothing of any importance had previously been discovered in the hills and mountains on that side of the valley; but the croppings mentioned are, as near as we can judge, the finest yet found in this locality.

Impurities in Copper.

From the circumstances that the refiner tests the quality of copper by forging a hot sample, it will be inferred that the effect of impurities upon its malleability and tenacity is more perceptible at a high than a low temperature. The foreign matters which commercial copper is liable to contain are arsenic, sulphur, antimony, tin, bismuth, lead, silver, iron and nickel. Of these sulphur and antimony are generally considered the most injurious in diminishing the malleability and tenacity of the metal. Arsenic is very commonly found in copper, amounting, in some of the Spanish copper, to as much as one part in a thousand, and was formerly supposed to be as injurious to the quality of the copper as antimony is, but modern experience has shown that copper may be easily rolled and drawn into wire even when it contains a considerable proportion of arsenic. A small proportion of tin is believed to increase the toughness of copper, but bismuth and nickel have the opposite effect.

The conducting power of copper for electricity is reduced in a most striking manner by the presence of foreign matter, so that in the construction of telegraphic apparatus it is important that the purest attainable copper wire should be employed.

Pure copper is scarcely inferior to silver in its conducting power, and the conducting power of the native copper from Lake Superior, which is almost pure, stands to that of pure copper in the proportion of 93 to 100, whilst the Australian (Burra Burra) copper, also very pure, has a conducting power of 89, and the Spanish copper, which contains much arsenic, has a conducting power only one-seventh of that of pure copper, or in the proportion of 14 to 100. The addition of a small proportion of phosphorus (about five parts in a thousand) to copper is found to harden it and somewhat to increase its tenacity; it is also said to render it less liable to corrosion when exposed to the action of seawater. By adding arsenic to copper, in about the proportion of one to ten, a white, somewhat malleable metal is obtained, which is not easily tarnished by air, and is much harder than copper. This compound, which is employed for clock dials and for thermometer and barometer scales, is made by heating five parts of copper clippings with two parts of white arsenic (arsenious acid), arranged in alternate layers and covered with common salt, in a covered earthen crucible.

The Mining Bureau.

At the session of the Legislature two years ago a concurrent resolution was passed to remove the specimens of ores at Sacramento to the State Mining Bureau in this city. It was found, however, that a new law would have to be framed. The matter, therefore, came up this session. The Mining Committee reported favorably, but the bill was rejected by a vote of 14 to 9.

It seems too bad that the collection should not be added to the already large one at the Bureau in this city; and the refusal looks like a "pointer" to indicate that the support the Bureau asks for will not be granted. The tax on sales of mining stock is now so low that the Bureau is running very short of funds. If it is to be maintained at all it should be properly supported. Mining has done a great deal for the State, but the State has done very little for mining. It ought at least maintain the Mining Bureau, which furnishes information for the mining community.

The trifle asked for should be voted. It looks strangely to see in a mining State like California a niggardly spirit prevail where this industry is concerned.

A NEW MINING CAMP.—Backbone Creek is looking up as a mining camp. Last Saturday 15 of the miners met and formed the Backbone mining district, appointing a committee to frame by-laws for their government, to report the first Saturday in May, until which time they will be governed by the United States mining laws. The mouth of Backbone creek is about 16 miles from Shasta, and the summit of the ridge about 20 miles. A road has been surveyed from the creek to the summit, with a grade of about 500 ft. to the mile, and this, with the railroad passing through it, will combine to make the camp one of prominence, especially as the district abounds in rich mineral deposits. —*Shasta Courier*.

Notes from Eureka, Nevada.

[From our Own Correspondent.]

EDITORS PRESS.—The past week has developed nothing new in the mines of this district. The Albion Company having paid up, all the excitement caused by unfounded rumors has subsided. The mine is looking well. The working force, however, has been decreased, but this is a point in favor of the stockholders, and as such is appreciated here. The delay in restarting the furnaces has been caused by the water pipes from the reservoirs having frozen. This will be remedied immediately. From the Richmond mine reports are still encouraging.

At the Eureka Con. old works there is nothing to note. At the new (Locan) shaft work has been resumed and the contractors are sinking at the rate of 15 ft. per week. The shaft is now down about 950 ft., and will be carried 250 ft. deeper, when a drift will be started towards the ledge line, which will be cut at a distance of about 200 ft. from the shaft, and, I think, 150 ft. below the 14th level in the old workings, now under water.

On Adams' Hill North

There are good signs of progress. A hoisting engine has been placed on the Williamsburg shaft, and work was resumed in the mine to-day. At the Boston and Eureka are also marks of improvement. On Adams Hill proper the lessees of the Horace Tony mine have been quite fortunate, having hit upon a perfect little bonanza, from which they have extracted several tons of fine quartz and carbonate ore. At the Eureka tunnel work is progressing as usual, and 60 tons of ore has been shipped to the furnaces during the past week. Yesterday I took a trip to Silverado mountain, where I found many prospectors actively at work. A shipment of ore from the Western Globe mine has just been made to the Richmond smelters, six tons of which yielded over \$300 per ton and the balance of four tons at the rate of \$150. It is thought that the Rescue mine will be started up soon, for which occasion a 22-horse power engine will be provided. This is a very valuable property, which, like others in its vicinity, has been closed down on account of mismanagement and the reckless expenditure of the company's money.

The Queen mine is at present yielding ore that is exceedingly rich, assaying from \$500 to \$1,500 per ton. The Silver Nugget mine is doing splendidly under a sub-lease. A tunnel run into the hill from the east side shows ore of high and low grade. A winze has been sunk on a vein to a depth of 100 feet, and from a drift run on it a large amount of ore has been extracted. Several shipments have been made from it, and another will be ready in a few days. Its neighbor, the Diagonal tunnel, enters the mountain from the east side 1,100 feet above the valley level. It runs about north 30° west for a distance of 700 feet, where the course changes to almost west, finally ending 1,000 feet from its face in a southerly direction. At a point 875 feet from the mouth is a vertical winze, from which a drift has been run almost even with the line of the tunnel. At the end of the latter is an open seam giving evidence of a near approach to ore. This portion of the mine will be cut up into sections, and not a spot as big as a half dollar will be left unprospected, for here rich developments are confidently anticipated. From the surface 350 ft. down to the tunnel level an incline shaft has been sunk, following ore almost the entire distance. A break occurred about 20 ft. above the tunnel level, leaving nothing but a closed seam to follow, but which it is thought is sufficient, as it still carries fine indications with it that in the early days of the camp were not understood. The Maryland mine in its vicinity was formerly owned by Mr. John A. Paxton and others, who, after getting several handsome dividends from it, sold to a company who, in place of using their capital to develop the mine, built a costly mill which took all the money in their treasury to pay for and then went into liquidation. Richard Berryman & Co. have had a lease of the Diagonal mine for the past three years, but until last May had not done any work on it. Since then five men have taken out ore, the net profit on which has reached the sum of \$5,046, and there are large masses of low grade ore still remaining in the chambers. One of the great advantages of prospecting on Silverado mountain is the facility with which the work can be done. As an instance, these men ran 817 feet of drifts and raises in six weeks, being equal to more than four feet per shift made by each man. Not a single pound of powder was used in the work. At the highest rate of wages paid to miners in this section of country this work has been done at a cost not exceeding one dollar per foot.

Attracted by the inducements offered, Mr. Berryman and a party of friends have secured 120 acres of the adjoining land in six locations, each being 1,500 feet long by 600 feet wide, which they will shortly proceed to develop by means of a tunnel to be run from a point near the base towards the highest peak of the mountain.

M. H. JOSEPH.

Eureka, Nev., January 29, 1883.

The inquest at Milwaukee on the Newhall house disaster has led to severe criticism of the Fire Department.

Montana Mining District.

Description of a Promising Region.

[Written for the PRESS by THOMAS F. CORTELL.]

The Montana mining district, Meagher Co., Montana Territory, lies in about 46° 50' north latitude, 110° 45' west longitude, and is situated on Main Belt river, about eight miles from its source. In the Little Belt mountains, a spur of the Rocky mountains, running in an easterly direction from the Missouri river, near "The Gate of the Mountains," accessible by good wagon road to White Sulphur Springs, the present county seat, a distance of 32 miles. To Helena, the Territorial capital, a distance of 87 miles; to Benton, head of navigation, 75 miles by road now in the course of construction, which can then be made available for machinery and supplies. The same road gives access to the Clendenin M. & S. Co.'s works, at Gold Run, Barker mining district, a distance of 20 miles. This district was discovered in July, 1881, by Messrs. Neilhart, Harley and O'Brien, the discovery being due to the impetus given to prospecting by the discovery of "Yo-Go," Barker and the Carpenter mining districts, the existence of silver ores having, however, been known since 1871, but the hostile attitude of the Indians prevented any investigation of this subject until 1879.

The Mines of this District

Are found in the mountain foothills in the immediate vicinity of Belt river, at an altitude of 4,000 to 5,000 ft. above sea level, being well watered by Belt river, a stream carrying at its lowest stage 1,000 inches miner's measure, intersecting the camp midway, having an average fall of 40 ft. to the 1,000 with numerous streams and runlets.

In the immediate vicinity of the camp there is no live timber, the country having been burnt off seven years ago, but this is amply compensated for by the vast forests which exist about five miles above camp up Belt river and O'Brien creek. The supplies from the latter are already accessible by the new wagon road to the county seat. Good mining timbers and good merchantable lumber can now be delivered at \$25 and \$30 per M in camp. Belt river itself furnishes ready access to the timber near its source, owing to the favorable nature of the stream for "driving" during the months of June, July and August. Cord wood can be delivered at \$3.50 in camp.

An inexhaustible supply of first-class hay can be delivered from Belt Park, three miles distant, at \$15 per ton.

The Supply of Coal

Is practically unlimited at a distance of 22 miles from camp. The coal pertains to the Dakota group, No. 1 (M. & H.), early cretaceous period, and underlies the whole country on the north and eastern foothills of the Little Belt mountains. The coal consists of three or more veins easily worked from the surface by means of adits and possesses valuable coking qualities, quite a desideratum for a smelting camp. (Coke as a fuel affording a regulus richer in silver but poorer in lead than when charcoal is employed, with shorter duration of the smelting period). The coal can now be obtained at \$5 per ton at the mines. This coal belt is now determined for a distance of 35 miles along the northern base of the mountains and is being extensively developed at Pittsburgh by Mr. John Castner, and near the mouth of the Big Littlestone creek by Mr. Ellis, and also at Sand Coulee by Messrs. McKean and Culbertson. Returning to the Montana district we find that

The Mineral Lodes

Consist, as far as yet prospected, of about 26 parallel veins, with a strike of about 10° east of north, intersecting the soft zones of granite, of which the country rock principally consists. The granite, which is principally porphyritic and hornblende, has a uniform dip to the south of from 30 to 40°, being cut at right angles by the veins above mentioned on the summit of "Black Baldy," and also in the southwestern part of the district, as shown in the map accompanying this article. This granite is capped by quartzose rock (an alluvial matrix of sandstone and quartz pebbles, evidently formed by heat and pressure). On the east bank of Fly creek is found (granite) diorite. When crossing this creek westerly this gives place to gneiss. South of the Frisco lode a belt of talcose slate disrupts the lodes. This belt commences at the river, and has there a breadth of 200 ft., extending southwesterly in a triangular shape until it reaches the quartzose reef, its base there having a width of 1,500 ft. South of the Reagan lode a body of porphyry is found about 1,200 ft. wide, the length being limited, the granite reappearing on O'Brien creek. East of "Black Baldy" the granite gives place to a slate rock containing no mineral veins.

The lodes of this district, without exception, are accompanied by porphyritic dykes which generally form the hanging walls of the lodes. In the neighborhood of the Queen of the Hills seems to be the central line of division between the two distinct grades of ore found in the district. Those to the east, including the Queen of the Hills, dipping west, contain silver glance, chlorides, sulphides and antimonial silvers (ruby and brittle silver), and the ores spangled with wire and native silver in foliated form, and in some instances wire silver twisted and entangling the ores from wall to wall with rich argentiferous galena, but principally antimonial ores rich in silver, with copper ores, such as erubescite, chalcopryite and carbonate; these last named ores are coming in at deep mining, and antimonial and copper ores will predominate

on development. These ores contain no gold, with the exception of the Hillsdale, which by fire assay gives a trace, and the Green and Weatherwax lodes, on Snow Creek, are said to contain \$40 to the ton, but I failed to find a trace, although gold is known to exist on Carpenter creek in the alluvial wash.

On the west of the Queen of the Hills the veins dipping east contain baser mineral; associated with some of those before mentioned are manganese, galena (light in silver), arsenical iron, zinc and antimonial blende, each of lead, etc.; but in the Huxley, Teton and Mountain Chief (on the one vein) the richer minerals, as associated with those of the eastern part of the district, with wire silver in discrete coils distributed in the small chambers in the matrix of the ores invariably associated with brittle silver and silver glance. Throughout the entire district manganese colors permeate the matrix of the ores as well as the granite and igneous dykes contiguous similar to the Summit Valley district (Butte). By glancing at the map an observer will be struck with the

Parallelism of the Veins.
The numerous favorable opportunities for run-

on the east, the hanging wall being porphyry, as before mentioned. The walls, as a rule, are soft, hard ones being the exception, with crystalline granular talcose gangue, often of a fine, impalpable texture. Proceeding to

A Description of the Mines.
What may be said of one may be said of many, and those at the present time being developed will, I think, be sufficient.

Commencing at the east end of the district, we find first, Banner and Bald Eagle, Fitzpatrick & Co.; elevation, 700 ft. above creek. This lode cuts the quartzose cap of this section. Width of vein 4 ft.; working test of ore from full width of vein, 47 ozs. silver; samples tested by Prof. Foss, C. M. and S. Co., 49 ozs. developed by shaft. Southern View and Kuntuck, Lake & McKaskal; elevation, 1,500 ft. at creek; character of ore, antimonial and carboniferous; sample assays 61 ozs. Seven hundred and fifty feet west we arrive at a line of fine locations on a vein showing some of the richest and most promising prospects of this district, at an elevation of 1,300 ft. above Belt river, and commencing at the Minnehaha and Montana. Bell, by Chamberlin, Macintosh & Co.; width

ery south the main vein is uncovered and shows a width of 8 ft. for some 200 ft., and south to the discovery of the Queen of Montana, by Rafferty & Co., where this vein is 10 ft. wide, and pay well distributed throughout the vein.

Deadwood and Frisco, by Neihart & Co. This vein has been determined for a distance of 3,500 ft. north from the Frisco, averages well, and is a bold vein carrying considerable copper.

Corra, by Mortenson & Co., "Os. Coxgis," by Coryell & Co., Massachusetts, by Hanna & Merion, and the Oregon, by Caruthers & Co., all on the same vein; bold vein, four feet wide and pay streak 22 inches; assays of sample \$71 throughout the vein at the Massachusetts shaft.

Queen of the Hills, Home Stake and O'Brien lodes, by Neihart, Harley & O'Brien. There are six locations on this vein, and ore exposed between walls of the same character. The extreme southerly locations are carbonate ores, while those of the Queen of the Hills as before described, while the matrix in the O'Brien lode is exclusively sulphate of baryta in massive form. These three locations present throughout their entire length the most extensive outcrop of ores that has been discov-

bodies of ore with little development, assay 22 ounces. Teton and Huxley, by O. C. Mortenson & Co. and Neihart & Co., are developed by two shafts; width of vein four and one-half feet; a pay streak 18 inches, and widening with development; samples \$245, \$273, \$860, \$920, \$940, \$160 and \$420. Ores from this mine treated by the C. M. & S. Co. net 284 ounces. The developments on these mines have shown as uniformly rich ore as any in the district.

The Samson, by P. Fehrenbach & Co.; width of vein, 10 ft. This location is remarkable for its strength, principally galena, antimony, zinc and manganese. Samples of this vein entire are 42 ozs. This mine is being developed by shaft and drift, the latter developing it to a depth of 500 ft. (on the vein), which everywhere shows remarkable strength.

The Hillside and Amelia, by D. B. Mackintosh & Co. Three or more parallel veins are contained in this surface ground. The Samson, running through the Hillside and Sunny South ground; width of vein, 10 ft.; character of ore same as Samson throughout. The main vein on the Amelia, as far as developed, discloses a width of 8 to 10 ft. crystallized quartz and spar, with

ing drifts on the mines, the remarkable continuity of the lodes and an examination of the leads on the ground show so many or shutes that the strength of the ledges are apparent at a glance. When we take into consideration that the openings on the veins hereinafter mentioned are contained in a space two and one-half miles square, and throughout that space in gulches or hills the veins preserve the same parallelism and continuity from an altitude of 750 to 2,500 ft., showing the depth to which these mines are now, and can be readily developed by drifts, rendering hoisting and pumping machinery almost unnecessary until they acquire 1,000 ft. of development. The dimensions of the claims are 1,500x600, where surface ground will admit and in several of the locations four parallel and distinct veins are included. The character of the gangue or matrix is principally heavy spar, throughout the entire district appearing in tabular form, also fibrous and compact, and resemble the barata artificially formed after the experimental researches of De Senamet and others, demonstrating its formation or production by the action of water at high temperatures and pressures; associated with this spar is quartz and feldspar.

The Width of the Veins
Vary from three to ten feet, increasing in width as developed. The strike, dip and extent of outcrop as mentioned above. The foot-walls are of dioritic character—impregnated with manganese in the lodes west of the Queen of the Hills, and hornblende granite in those

of vein, 5 ft. 5 inches; samples assay \$421.80, \$860, \$114 and \$1,219.80. Next we find the Wide Awake and Fitzpatrick, by Fitzpatrick, Largent Bros. & Co.; width of vein, 5 ft., with very rich pay streak 2 ft. 4 inches; developed by adit; assays by ton \$883, \$1,067, \$1,164, \$1,518 and \$1,250; U. S. Assay Office, Helena, \$3, 078.95. Ores from the Fitzpatrick treated by the C. M. and S. Co. netted 250 ozs. (full width of vein).

Maud S., by Chamberlin & Bell; width of vein, 14 ft.; samples 56 ozs.; one foot samples 350 ozs.; St. Julien, by D. B. Macintosh & Sanborne, same as Maud S.; Dexter and Alexander, same, with manganese appearing in these ores; Atlantis & Boss, Neihart, Barrett & Co.; on this vein there are five locations; character of the ores, gray carbonates, rich in silver, developed by shaft; assays, \$71.10, \$87.30 (for samples); width of vein, 4 ft. 8 inches.

North Star and Roseanna, by Power, Lamb & Co., and Darwin, by Neihart & Co.; width of vein, 3½ ft. No developments as yet.

Yellow Jacket and Helena, Neihart & Co.; width of vein not known in shaft, but is in five feet of ore and no hanging wall; assays 22, 26, 41 ounces; by Foss; sample by McVicar, 136 ounces. South Carolina and Texas, by Neihart & Co., vein eight feet wide in shaft and drift; sample of vein, \$46.75, 112.20 ounces. This location consists of one main vein dipping east, and a vein parallel on the west dipping to the main vein, and two side veins east dipping west to the main vein; 180 ft. from the discov-

ered for years in any district. The samples taken from the several drifts and shafts along the vein range 335, 644, 492, 111, 101½, 85, 52, 97, 275 ounces, and highest for surface ores \$40 ounces. A drift is now being run on the Home-stake on the vein, and will be continued for 300 ft. this winter. They are now in 138 ft., and the ores assay from 60 to 4,800 ounces to the ton. It is intended to push this drift the entire length of the three locations. They have now reached a depth of 71 ft., and will when they reach the O'Brien, with 1,700 ft. of drift, be 700 ft. in depth. They are driving on the vein, which is now 5 ft. 8 inches in the face. Here can be seen the wire, ruby and brittle silver, with the silver glance in beautiful fibrous matrix of baryta. These mines are

Owned by Good Practical Miners.
Who are prosecuting the work in person. Commencing at the north boundary of the O'Brien location we find the Ed. Man and Mountain locations running 15° west of north, by Man & Caruthers. This vein at the bottom of the working shaft shows a width of 10 ft. in the crosscut. The gangue is highly crystallized quartz, containing galena and gray carbonates, together with other high grade minerals; samples of ore the entire width assay 38 ounces; a rich streak next the hanging wall assays 684 ounces. The Little Treasure, by Hamilton & Neihart, a new find, with little development; vein three and one-half feet wide, antimonial ores assaying 81 ounces.

The Great Western and Hercules, large

high-grade galena samples of pay streak \$303, and it is likely that this vein traces the Hillside and Sunny South grounds, Montana, by Crandal & Co.; this vein has been determined for a distance of 25,000 ft.; character of mineral, argentiferous galena; width of vein, 4 ft. 8 inches. Samples assay 91 ounces. The Huron, Gothrob, Rosa, Redrock and First Discovery, in the westerly part of the district, will shortly be developed and can then be reviewed; their general character is galena associated with richest minerals.

From the foregoing description it will be seen that accurate survey and

Close Investigation Has Been Made
Of these mines and their surroundings; that the natural facilities for mining, drainage and reduction of ores, and as an ore-producing district, is unexcelled. Advantages exist for transportation of machinery and supplies, by water or rail, the latter more especially, as they have faithfully promised the N. P. R. R. at Townsend, 65 miles distant, in July next, and to that point a good wagon road is already completed from the mines via the county seat.

It is proper to mention that the town of Neihart is already laid out, and promises at no distant day to be a flourishing community.

Space not permitting, I have deferred a description of the Carpenter district until the following month, when I expect to be able to report the Yo-Go, Woodhirst, Shaw, Barker and other mining districts of the northern part of Montana.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Grant and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x30 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x30. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

MILL AND MINING MACHINERY.

F. A. HUNTINGTON,

No. 45 Fremont Street, - - - San Francisco, Cal.

Oscillating Stamp Mill.

It has no Stems, Cams, or Tappets, and adjusts itself to the wear of the Shoes and Dies.

For simplicity, economy, durability and effective working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power. Awarded First Premium and Medal at Mechanics' Fair, S. F., 1880.

Manufactured by F. A. HUNTINGTON, FRASER & CHALMERS, 45 Fremont St., S. F., Cal. 145 Fulton St., Chicago, Ill. Improved Patent Grinding and Amalgamating Pans, Concentrators and Gold Amalgamators; also, Steam Engines and Mining Machinery of all kinds. Send for circulars.

F. A. HUNTINGTON,

45 Fremont Street, San Francisco, Cal.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in a very short time. One machine will concentrate the tailings from a five-stamp battery.

Send for Circulars.

SHINGLE MACHINE.

For simplicity, durability and rapidity of action, these Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

SAWMILL MACHINERY,

Of all descriptions made to order.

F. A. HUNTINGTON,

No. 45 Fremont Street, San Francisco

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

—OR—

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

Room 7, 109 California Street, - - - - - SAN FRANCISCO, CAL.

A CHEAP ORE PULVERIZER.

We have on sale, at a very low price, a RUTHERFORD ORE PULVERIZER, which is in perfectly good order in a strong frame, with pulley, etc., all ready for work.

It has only been used a couple of months, and is as Good as New.

This is a good opportunity for anyone wanting a Pulverizer of moderate capacity for a low price. Address,

DEWEY & CO.,
252 Market St., S. F.

FIGARI & RICHMOND'S BOILER AND TUBE COMPOUND.

We guarantee our COMPOUND to remove all scale and prevent any more being deposited. The COMPOUND forming a glazed surface on the iron, to which no scale will adhere and which preserves the iron.

The preparation is strictly vegetable, and is warranted to do all that is claimed for it without injury to the metal. Send for a circular.

271,148.—STRAW-BURNING BOILER—Joseph Stevens, S. F.
271,159.—DRAG SAW—Charles Thompson, Corvallis, Oregon.
271,098.—FILTER—James Miller, Oakland, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

COMBINED WRENCH AND PINCHERS.—Samuel S. Willmer, Anderson, Shasta county. No. 270,356. Dated January 9, 1883. The stock or body of the tool consists of a hollow casing open upon one side. At one end it has formed with, or has secured to it, the stationary joint of an ordinary wrench. At its other end it has a jaw of the pinchers. The movable jaw of the wrench is adapted to slide upon the shank of the stationary jaw. To use the wrench a pin is pressed to one side which disengages a part from the movable shank, and the movable jaw may be set at any point. A spring receives the jaw at the point set. To use the other end of the tool a swinging jaw is opened away from the other, or stationary jaw, and its limit is defined by the position of a peculiar ring, adapted to slide backward or forward. In this tool the inventor has combined two useful ones, both of which are frequently needed in the same work. In places where the wrench end cannot be used on a bolt, the pinchers end can be employed, as where the tool must be turned on its longitudinal axis. It is easily constructed and may be repaired without trouble when necessary.

REVOLVING SPRINKLER.—John H. Henderson and Emilio Schutz, Sierra Buttes, Sierra county. Dated January 16, 1883. No. 270,664. This improved sprinkler is of that class in which the revolution is obtained by the unequal pressure of escaping water upon the familiar principle embodied in Barker's wheel. The invention consists in providing revolving arms, each with a single nozzle at their outer ends, one of which is directed to discharge its water to fall inside of the circle described by the ends of the revolving arms, and the other to discharge outside of said circle, whereby both the center and outside of the circle to be sprinkled is supplied. With the nozzles are connected dashing devices, whereby the water is spread over the surface in any desired fineness of spray, said dashers being also made by changes in position to retard revolution by effecting reaction. The object of the invention is to provide a revolving sprinkler which shall spread the water efficiently, is not liable to become clogged, and which may be operated at varying rates of speed, irrespective of the head or pressure of water from the main source.

SEWING MACHINE.—Edward Kohler, Oakland, assignor of part interest to H. P. Eayrs and M. Grunewald. Dated Jan. 16, 1883. No. 270,814. This is an improvement in sewing machines intended more especially for sewing heavy fabrics, such as carpets or bags. The invention consists in certain improvements in detail and various novel features of construction. In the sewing of bags by this machine the operation can be performed with great rapidity, because it is not necessary after finishing each bag to stop the machine and adjust any of its parts before commencing work on another bag. The machine will continue to form the interlocking stitch whether the fabric be in position below the presser foot or not, and any number of bags may thus be sewed and connected together by stitching, which may afterwards be separated as desired.

COOKING STOVE.—Charles H. Dunton, Oakland. Dated Jan. 16, 1883. No. 270,766. The improvements consist in the novel construction and arrangement of a round fireplace with relation to the stove, and in the employment of a vertically adjustable grate in the fireplace, together with a means of adjusting and holding the same. The heat from the fireplace acts upon the oven through its front wall, and also through the entire extent of its top, and at the same time is utilized for cooking on top of the stove. It is, therefore, well directed for its purpose, accomplishing its results with economy.

PARALYTIC strokes, heart disease, and kidney affections, prevented by the use of Brown's Iron Bitters.

STRENGTH

to vigorously push a business, strength to study a profession, strength to regulate a household, strength to do a day's labor without physical pain. All this represents what is wanted, in the often heard expression, "Oh! I wish I had the strength!" If you are broken down, have not energy, or feel as if life was hardly worth living, you can be relieved and restored to robust health and strength by taking BROWN'S IRON BITTERS, which is a true tonic—a medicine universally recommended for all wasting diseases.

509 N. Fremont St., Baltimore

During the war I was injured in the stomach by a piece of a shell, and have suffered from it ever since. About four years ago it brought on paralysis, which kept me in bed six months, and the best doctors in the city said I could not live. I suffered fearfully from indigestion, and for over two years could not eat solid food and for a large portion of the time was unable to retain even liquid nourishment. I tried Brown's Iron Bitters and now after taking two bottles I am able to get up and go around and am rapidly improving.

G. DECKER.

BROWN'S IRON BITTERS is a complete and sure remedy for Indigestion, Dyspepsia, Malaria, Weakness and all diseases requiring a true, reliable, non-alcoholic tonic. It enriches the blood, gives new life to the muscles and tone to the nerves.

Attention, Boiler-makers and Engineers!

Just Out! The Best Work of its Class Published!

The Theoretical and Practical Boiler-maker.

By SAMUEL NICHOLS, Foreman Boiler-maker. Embraces full details of Geometry and Orthographic Projection as applied to Boilermaking; also to make, draw, design, and set out all kinds of Templet Work, as Ellipses, Cones, Truncated Cones, Oblique Cones, Frustums of Cones, Chimney Bottoms, Cylinders, Cylinder and Cone, Cylinder and Sphere, Cylinder connected with Curved Tube, Cylinder and Angular Tube, Cylinder with Spiral Staircase, Hip Roof and Chimney, Tubes, Angular Tubes, T Tubes, Raper Tubes, Curved Tubes, Quadrant Tubes, Downtake Tubes, Flues, Spheres, Domes, etc., of every kind, illustrated with 74 diagrams, including a full solution of all the problems relating to Boilermaking. The Cylinder, its sections, penetration, and development; Welding and Construction, Drilling, Punching, Riveting, Single and Double Riveted Lap and Butt Joints, with Single and Double Strips, Diameter, Spacing, Strength, and Pitch of Rivets; Strength and Pitch of Stays. On Locomotive, Marine, Cylinder, Multitubular, and Egg-ended Boilers; Power of Boilers; Heating Surface of Boiler Tubes in square feet; the Lever Safety-Valve; the Cylinder; the Sphere; Area of Fire Grates; Quantity of Steam required for an Engine; Flat Surfaces, Boiler Explosions; Practical Notes on Steam; Properties of Saturated Steam; Proportion of Boilers; Bursting pressure of lap-jointed Wrought Iron Cylindrical Boilers; Collapsing pressure of Wrought Iron Cylindrical Tubes of varying thicknesses. Practical Rules, Instruction, and Memoranda for Boilermakers; Material for Boiler Construction; Weight, Strength, and Dimensions of Wrought Iron Boiler-plates and Iron Bars; Strength of Steel Plates, treatment of do.; Strength of Plates at different temperatures; Strength of Ropes and Chains; Properties of Metals; Weight of Wrought Iron Cylinders per lineal foot of any given diameter and thickness; Angle Iron Hoops; Diam., Cir. and Areas of Circles, with detailed explanations relating to Boiler Construction; to determine thickness of Boiler Heads, Cylinder Covers, etc. Mensuration as applied to Boilermaking; Fuel Valves, combustion of Fuel, Evaporation of Water; Setting Boilers, Installation, Boiler Scale Preventives, 35 kinds; Heating equivalents, Weight of Water; Expansion of Water; Squares, Cubes, and Roots; Fusing Points of Metals; Conducting Powers of Metals; Useful Definitions, Reference Tables (83 pages) for Boilermakers, Engineers, Smiths, etc. 1 vol. 12mo, extra cloth. Mailed post free to any address on receipt of \$2.50. Send for 25 page Illustrated Catalogue of 3000 Standard Books on every subject. Agents wanted. National Book Company, 73 Beekman Street, New York.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL.

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

THOS. F. ROWLAND, Sole Man'fr, Brooklyn, N. Y.

MINERS' HORSE-WHIM

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The standard of the whim is bolted to bed timber, thus avoiding all frame work. When required these whims are made in sections to pack on mules.

NATIONAL DUPLEX COMPRESSOR.

KNIGHT'S
Mining Water Wheel.
OVER 200 IN USE IN CAL.

PACIFIC MACHINERY DEPOT.

H. P. GREGORY & CO.,

Importers and Dealers in Machinery and Supplies.
Nos. 2 and 4 California Street, S. F.

The Korting's Injector is the simplest, cheapest and best in use. Will draft its own water, hot or cold, and feed under varying pressure. Send for Circular.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS. All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

- No. 1.—The most Powerful Explosive Compound now in use here.
- No. 2.—Surpasses in strength any Powder of its class ever manufactured.
- No. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much faster. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

THE JOHN A. ROEBLING'S SONS CO.,

Manufacturers of

WIRE ROPE and WIRE

Of Every Description.

For Inclined Planes, Standing Ship Rigging, Suspension Bridges, Ferries; for Mines and all kinds of Heavy Hoisting; for Stays and Guys on Derricks, Cranes and Shears; for Tiers, Sawmills, Sash Cords, Lightning Conductors, etc. Galvanized and Plain Telegraph Wire.

VOLUME XLVI.
Number 6.

The State Mining Bureau.

While in other States and Territories associations are being formed for the purpose of collecting statistics and information about mines, and for erecting State or Territorial museums for the collection and preservation of ores, minerals, etc., in California, the oldest of all the mining States; the one that has produced the most bullion, and has been producing it the longest; whose mining machinery goes all over the world; whose methods and processes are everywhere followed; and which has a world-wide reputation as a mining region, the institution already founded, well under way and well equipped is about to be allowed to die for want of a beggarly appropriation which should be freely given.

Although many persons express themselves as friendly to the State Mining Bureau, measures for its relief are unsatisfactory, slow and indefinite. The Legislature refuses to add to the collection that already in existence at Sacramento, and so far nothing has been done towards making an appropriation to its support. Moreover, there does not seem to be any favorable signs of an appropriation being made.

The Bureau which was organized to foster legitimate mining has been compelled to exist on the proceeds of a tax on the transfer of mining stocks, which in itself was a ridiculous state of things. But now, that the mining stock business has dwindled to nothing, it cannot be kept up on that. For the last quarter the revenue was some \$1,700, which barely pays rent and the State Mineralogist's salary.

It has come to this, that if an appropriation is not made by the Legislature the Bureau must close. The collection will have to be packed up and stored until a more liberal spirit pervades the law-makers of the State.

It is, of course, but just and right that all sources of expenditure be closely scrutinized. In this instance, however, a committee has come down, examined the museum, and the members have expressed themselves to the effect that the institution is doing good.

It seems, therefore, as if something should be done to aid the Mining Bureau, or else abolish it altogether, and not let it drag on, half supported, and in a shape that its objects cannot possibly be accomplished. The friends of mining and of industrial progress in the Legislature should give this subject proper attention, and consider the claims the mining interests have to be properly represented before the people.

PATENTING BY A PART OWNER. A Colorado miner, who owned four-fifths of a lode claim and desired to have the same patented, but to which the co-owner refused his consent, asked the General Land Office how to proceed. He was advised "that there seems to exist no good reason why you may not institute proceedings for patent in the joint name of yourself and co-owner, either with or without his consent. You may be able to enforce contribution from such co-owner for his proper proportion of the expenses of patenting in the courts. You cannot receive patent for an undivided interest, and this office has no authority to compel a co-owner to join in an application."

PARTIES are still at work mining in the bed of the South Fork of Feather River, near Enterprise. They have not been disturbed by water this winter.

Manufacture of Ice.

There has been in practical operation in Phoenix, Arizona, for some four years past an ice machine invented by Samuel D. Lount, of that place, which has accomplished such good results that similar machines have been put at work at Globe, Arizona, Guaymas, Mexico and other places, and machines of larger capacity are now being made here.

These machines to which we refer can be made of any desired capacity. The first one put up only made 1,400 lbs. per day, but 10 or 15 or

or vapor it will soon be decomposed and fail to perform the service for which it is used, thus necessitating the frequent introduction of a fresh supply, and the advantage of keeping the wearing parts constantly bathed with a pure and cool lubricant will be readily seen.

This object Mr. Lount accomplishes by the peculiar arrangement of the compression cylinder and piston. The general appearance of a double machine, such as is now being made at the Etna Iron Works, in this city, is shown in the large engraving. Fig. 2, is a section of the cylinder of the pump.

COMPRESSOR FOR MINING WORK OR ICE MANUFACTURE.

more tons can be made. There is no new principle involved in the manufacture of ice. It is in carrying out certain details in an improved manner that constitutes Mr. Lount's claims on the new machine—details, which, in effect, make the manufacture of ice on the old principles much less expensive and less troublesome.

One of the main features in Mr. Lount's method is the peculiar compressing pump he uses, so constructed that the packing and the surfaces which are exposed to friction are not brought into contact with the compressed and heated air or vapor. Compressing pumps, when working under a heavy pressure, require abundant lubrication, and if the lubricant employed is allowed to come in contact with the heated air

or vapor it will soon be decomposed and fail to perform the service for which it is used, thus necessitating the frequent introduction of a fresh supply, and the advantage of keeping the wearing parts constantly bathed with a pure and cool lubricant will be readily seen. This object Mr. Lount accomplishes by the peculiar arrangement of the compression cylinder and piston. The general appearance of a double machine, such as is now being made at the Etna Iron Works, in this city, is shown in the large engraving. Fig. 2, is a section of the cylinder of the pump.

When the piston, *B*, is moved upward, the

air or vapor to be compressed is drawn from the outlet pipe, *E*, through the pipes, or chambers, *b, b*, into the space below the piston, and on the return stroke of the piston, the air or vapor passes through the cup inside the piston, and the valve, *C*, to the compression chamber above the piston, where it is compressed by the following stroke of the piston and forced through the valve, *D*, to the outlet pipe, *F*.

Now, the heat which is generated by compression, is all developed at the upper end of the cylinder, *A*. The upper and closed end of the piston, *B*, passes at each stroke through this heated chamber, but the packing ring, *pp*, being separated from this closed end by the thin wall of the cup, cannot become heated, for it will be observed that the interior of the piston, *B*, is always in contact with the uncompressed, and consequently cool air or vapor, which readily abstracts the heat that is conducted from the compressing chamber by the metal of the piston and cylinder, from the thin wall surrounding the cup, and also from the lower portion of the cylinder, *A*, after which it is transferred to the compressing chamber above before it can accumulate sufficient heat to decompose the lubricant or damage any of the parts exposed to friction.

The outlet pipe, *E*, does not communicate directly with the lower end of the cylinder, *A*, but through one or more pipes, *b, b*, which pipes terminate below the closed end of the cup-shaped piston, when said piston is at the lowest part of its stroke, thus forming a reservoir at the lower end of the cylinder, *A*, and this reservoir is kept full, or partly full, of any lubricating liquid which will not be disturbed by the air or vapor passing through the pump, and it will be kept at all times cool by the passage of the air or vapor through the said pipes, *b, b*. This liquid is always in contact with the piston-rod, and the lower end of the piston, *B*, and the packing ring, *p, p*, is immersed in said liquid at each stroke of the piston.

A compressing pump constructed in this manner does not require any water jacket, or the application of any cooling medium whatever, except the air or vapor which is forced through the pump; and another important advantage is that the treatment employed is always applied with certainty and in abundance to all the wearing parts, while said lubricant is not allowed access to the compressing chamber of the pump.

Mr. Lount has operated a pump of this description for compressing the vapor of ammonia to a tension of 120 to 180 lbs. to the square inch, continuously day and night, without ever having the piston rod or lower half of the cylinder at a higher temperature than blood heat, although the upper end of the cylinder was at a temperature much above the boiling point of water. With the machine just completed in this city, and running some little time, and compressing air to 200 lbs., the writer could feel the very great difference in this respect, the piston rod and lower part of the cylinder being merely blood warm. This pump was run at times under an air pressure of 340 lbs. with no special heat on the parts exposed to friction.

This in effect, is the compressing apparatus for compressing the vapors of ammonia. It can, as will be readily seen, be used for compressing air for mines, and some will be manufactured for this purpose by the Etna Iron Works Co., of this city. The general arrangement can be seen by the engraving.

(CONTINUED ON PAGE 96.)

Denver Exposition—No. 24.

(Editorial Correspondence.)

We conclude our series of letters on the Denver Exposition with a brief reference to Utah and Her Exhibit.

Discoveries of gold, silver, lead and copper in Utah were made as early as 1863, but the refractory nature of the ores, the great cost of transportation, and the opposition of the Mormon authorities to the influx of a general mining population, discouraged for many years any very extensive attempts to develop the mines. But the existence of a new and promising mining field, with favorable reports from enterprising prospectors, who always bid defiance to danger and natural obstacles, soon began to attract the attention of capitalists, by whom alone it was possible that the mines could be developed, and in 1870 operations on a large scale were undertaken. From that time to this the mining interests of Utah have been constantly progressing until now it is one of the leading mining fields of the Union, the reported yield of which, for 1882 was \$8,143,175 in bullion, which is an increase of \$789,000 over the report for the previous year, while the prospect of the future output of bullion is of the most promising character. The total output of Utah up to date has been about \$56,000,000, including lead.

Topographical Features of Utah.

Utah is divided nearly throughout its center by the main ridge of the Wahsatch mountains, which cross the Territory diagonally, into two nearly equal divisions, from its northeast to its southwest corner; the eastern portion is drained by the Colorado river, while the western has a drainage peculiar to itself, with no outlet to the sea, but either centering in Salt Lake or sinking in the desert sands of the "Great Salt Lake Basin." The Wasatch mountains seldom reach the perpetual snow line, and are much lower than the Rocky mountain divide in Colorado. Nearly every portion of this mountain range, with its spurs upon both sides, is rich in minerals. The extent of the mineral region cannot be less than some 600 miles, in a diagonal direction through the State, by an average breadth of from 150 to 200 miles, affording a vast and promising field for the prospector and miner. Throughout this extent of country not less than 80 mining camps or centers of that industry have been established.

The Mines of Utah

Are everywhere being thoroughly developed and energetically worked. Railroad facilities are being introduced to further facilitate development, and capital is coming in freely for all needed purposes. A large number of reduction works have been erected at important centers, and others are being erected or projected as rapidly as the nature of the developments in progress seem to warrant. The chief mining points are Park City, Cottonwood, American Fork, Saady, Bingham, Tintic, Stockton, Frisco and Silver Reef.

Park City, which leads the above list, is also the leading mine of Utah, and one of the few great mines of the world. This mine was fully noticed in our mining review of last week, as were many other leading mines in the Territory, hence particular reference to individual mines is not needed in this connection.

The Sandstone Mines

Of Washington county form one of the most interesting features connected with mining in Utah. These mines have attracted much attention from mining experts and scientists in general. The exhibits from these mines at the Denver Exposition were very interesting and suggestive. The occurrence of silver in sandstone at this locality has very much modified the opinions of geologists in regard to the deposit of the precious metals. But as these mines and the philosophy of their mineral contents has already been fully discussed in past issues of the MINING AND SCIENTIFIC PRESS, there is no occasion for its repetition here.

The Utah Exhibit.

The display made by Utah was one of the most complete and best arranged in the building. In extent it comprised over 200 packages, and in bulk it filled about two cars. The exhibition was well arranged, classified and labeled with good taste and intelligence. The selection of Professor Clayton as Commissioner was fortunate, as no other man in the Territory was so well fitted for the position as the Professor. He was most ably assisted by Mr. A. Zeenlehar, formerly of this city, but for several years past a resident of Utah.

The display of silver in sandstone and petrified wood attracted much attention. In addition to the precious metals shown there were also fine specimens of coal, sulphur, marble, gypsum, iron, lead, copper, etc.

Antimony, Bismuth, Sulphur, &c.

Among the exhibits was a collection of beautiful specimens of antimony from the American antimony works, at Salt Lake, assaying as high as 71.32% of antimony, carrying 28.13% of sulphur, with scarce a trace of arsenic, lead or any of the other substances which usually deteriorate this ore. The formula for pure sulphide of antimony or stibnite is antimony, 71.4; sulphur, 28.6. The company own a group of 25 claims in Coyote district, Iron county. They showed a single specimen which weighed about 3,000 pounds, and assayed 60% of antimony. They also exhibited three cases

of their manufactures in metal and fine material from their manufactory near Salt Lake.

Cinnabar was shown from the Geyser mine, Tooele county. Sulphur was shown almost pure from the immense beds of that material in Beaver county, one specimen weighing over 500 pounds.

Native sulphur, with vein formations carrying about 30 ounces of silver and \$2 in free gold per ton, was shown from a mine in Bingham county. Specimens of bismuth were exhibited containing as high as 50% of that metal, and 630 ounces of silver to the ton of ore. This class of ore is found in several localities at Tintic, Detroit, Granite, etc. Bismuth is beginning to be an important metal for use in the arts, and has hitherto been imported from Europe. There is no doubt but that in the near future the Tintic mines will furnish an abundant supply. Utah, as all the world knows, abounds in salt. It occurs there in mountain masses, and the Salt Lake contains enough, perhaps, for the supply of the world. Of course, this article was not overlooked on account of its abundance. Some beautiful specimens were shown.

Sulphate of soda (glauber salts), a by-product in the manufacture of salt, was shown in quantity. Black shell marble from near Salt Lake was shown, also white and mottled marbles from San Francisco mining district, Detroit mining district, Provo valley, Wasatch mines and Preuss mining district. Those marbles are beautiful and very suitable for building, mantels, statuary and sculpture. The Utah quarries are immense, and there is enough in sight to furnish marble fronts for all houses on this whole Western slope.

Gypsum of excellent quality from several locations was shown. There are large deposits of this material in various parts of Utah. Excellent building stone from the freestone quarries in San Pete county and several other localities were shown.

Bituminous slate and other rocks saturated with oil were shown, together with the somewhat rare mineral, cerite—mineral wax—was also on exhibition. These minerals are said to exist in large quantities in some parts of Utah, although they have not as yet been developed to any considerable extent.

Copper.

The Tintic mountains contain vast storehouses of mixed copper, gold and silver ores, which are reduced to matte by the furnaces of the Mammoth Mining Co. in Tintic valley, under the general management of Mr. W. H. H. Bowers, a thoroughly educated and eminently practical mining and mechanical engineer. The Utah Western railroad passes through these mountains, affording abundant means of transportation. It is said that a few miles west of this locality, and near the eastern boundary line of the great desert, a mineralized zone extends for 60 miles east and west, containing true fissure veins, carrying mixed copper, silver and gold, compared with which the copper mines of Chili and Lake Superior will some day fall into insignificance.

Coal.

The coal fields of Utah were also represented. Those fields are very extensive, occurring at intervals throughout the entire slopes and plateau of the great dividing ridge of the Territory—the Wasatch—from its northern to its southern border. These coal fields embrace thousands of square miles, and contain coal in abundance for years to come. The geological era to which they belong is an open question. They have been pronounced by "coal experts" as belonging to the Cretaceous and Tertiary eras, and are largely lignites. A. P. Bouton, M. E., reporting on the coal veins of the San Pete valley, says: "The coal is of a dark brown color, highly stratified, as it is naturally would be so near the surface, having been exposed for vast ages of time to the oxidizing force of nature, carrying in their lines of fracture their scales of sulphate of lime, increasing the percentage of ash. These mineral salts must of necessity prevail here, being deposited by water carrying minerals in solution. The salts disappear very rapidly in going in on the veins, and in proportion as you get beyond the brecciated rocks overlying the outcrop, through which these mineral waters have been filtered. Samples obtained about forty feet from the surface, by analysis yield as follows:

Moisture	1.8
B tumen	34.2
Coke (exclusive of ash)	50.7
Ash	13.3
Total	100.

The above analysis indicates a very superior bituminous coal. It yields a coke but little inferior to that obtained from the best Cumberland coal. In addition to the above the coal measures of Pleasant valley and Castle valley have been quite extensively developed, and are said to be of a very superior character. These three deposits are nearly in the center of the Territory, just south of Salt Lake City, and near to the line of the Denver & Rio Grande and the Utah Central railroads—the former passing just east and the latter just west of the mines, and with both of which they will all soon be connected by branch railroads. A branch has already been constructed to the Pleasant valley mines.

Iron.

The iron deposits of Utah are immense. They form whole mountains, and have been pronounced by good authority to be among the most remarkable deposits of that mineral on the continent. Save the spathic, all the ores of iron occur in Utah everywhere, the heaviest and richest deposits being in Iron county. Hematites

and magnetites crop out there in a belt two miles wide and 16 long in great masses. One called the "Blowout" contains 3,000,000 tons in sight. Prof. Newberry, after analyzing, says many of the deposits are first-class Bessemer ores. Water and coal are plenty and convenient, and wood for charcoal. Important iron deposits occur at Tintic, in Cache valley, about Ogden, and in other localities. The establishment of

Metallurgical and Smelting Works

In Utah has been entered upon on a large scale, and already forms a feature of prominent importance in the present, which must soon be largely increased for the future development of the industry into permanent prosperity. The ores and fuels are in quite close juxtaposition, while water and timber are also found in abundance.

The great smelters not directly connected with mines are the Germania, the Hanauer, the Mingo and the Mammoth Mining Co.'s works at Tintic, already alluded to. In addition to these another large smelting company is about being organized in the Tintic Valley for the reduction of the ores of the Tintic mountains. The increasing demand upon the smelting works of Utah may be inferred from the last reports of the Germania smelting works. The refined lead turned out by those works in 1881 was 1,323 tons; in 1882 it was 4,107 tons. The Hanauer furnace produced 1,508 tons in 1881 and 2,801 tons in 1882.

The Future of Utah.

It requires no prophetic gift to foretell the advent in the near future of an era of great prosperity and increase in the mining industries of Utah. The day of prospecting has comparatively passed away. Development and permanent work is now the order. Her coal fields may be measured by townships and almost by counties. Her iron ores are rich and abundant. Indeed, the entire basin of Utah has been a vast laboratory, where the grand processes of nature have been carried on for countless ages upon a most extensive scale, even for nature's work, and perhaps nowhere else on the globe equalled in extent and variety. Among the results we have, besides gold and silver, copper, lead, iron coal, antimony, bismuth, cinnabar, sulphur, marble, gypsum, salt, soda, oil, mineral wax, etc. The climate of Utah is singularly mild, which, with the abundance of agricultural land rich and well watered or favorably located for irrigation, will enable her population, even when it reaches millions, to produce their own breadstuffs to a large extent, while her extensive plains offer pasturage throughout the year for immense herds of sheep, cattle and horses. In short, Utah has natural resources which must eventually place her in the very foremost rank in the grand array of American States.

W. B. EWER.

Hydraulic Pumps.

The Eureka Machinery at Work.

Our regular correspondent at Eureka last week visited the new works of the Eureka Consolidated mine, in company with Superintendent Read, and sends us the following description of the hydraulic pumping machinery:

We were supplied with rubber clothing, and getting aboard of "Jumbo," were lowered to the bottom of the immense shaft. Here we stood for a while watching the men at work, standing a foot deep in water and streams pouring down on our heads. It was coming into the shaft at the rate of 200 gallons per minute. Here the necessity of heavy machinery is quite apparent. It has been supplied, and is proving all that has been claimed for it. The main feature of the new machinery is

The Hydraulic Sinking Pump.

It will be remembered that during the discussion between engineers some years ago as to whether hydraulic pumping machinery could be successfully introduced to drain the flooded mines on the Comstock, the point was maintained that while hydraulic machinery was suitable for ordinary pumping purposes, it would be impossible to operate a sinking pump by hydraulics, and that even if the latter were introduced the sinking pump would still have to be worked by the old spear rod system. Mr. Joseph Moore, of the Risdon Iron Works, San Francisco, took exceptions to this view, but at that time had no opportunity of putting his ideas into practice. Since then, however, he has drawn designs for and patented the sinking pump now successfully working at the Eureka Con. Mine. In the absence of drawings which I have seen, but unfortunately cannot present, a brief description of the manner in which it is operated will be interesting.

The pump proper follows the shaft down on vertical guides, and the motion to its plunger is transmitted by means of a set of actuating rams situated on the 600 level. The sinking pump consists of two cloisters of three cylinders each, the plungers of which are attached to a single crosshead between each set of cylinders; the cylinders, three in number, as stated, are lying side by side, with the working barrel of the sinking pump in the middle, and the pressure rams on each side of it.

On the 600 station are the actuating rams, consisting also of three cylinders lying horizontally side by side, the center one being the power cylinder, and the two on either side being connected by pipes to the side rams of the sinking pump. Now, in order to give motion

to the latter, the actuating rams on the 600 station are started, and we have in motion a column of water working upwards and downwards, carrying with it the plungers of the sinking pump. The latter, therefore, consists of no more mechanism than three plain cylinders that are entirely operated from the 600 station. The advantage of this system has been recently illustrated. During the last three months, through which time the new accumulator was in course of erection, the entire machinery stood idle, and the sinking pump, at a depth of nearly 1,000 ft. below the surface, became entirely submerged. As soon as the erection of the new accumulator was completed, and the pressure raised within it, the sinking pump was started from the 600 station by the pressure being admitted to the actuating rams, and in a few hours the shaft was drained.

The sinking pump, which had been out of sight for a period of three months, came to view again, unimpaired and in as good condition as ever. By means of a small valve the whole pump can be raised or lowered as required. When the miners are ready to discharge a blast, it is raised clear out of the way of flying rocks, and as soon as it is safe to do so, it is again lowered into place at the bottom of the shaft, and pumping is resumed without further interruption. No time is lost. The whole thing moves like clock-work, and is remarkable for its easy motion. The miners, heretofore prejudiced in favor of the old-style Cornish pumps, now universally acknowledge the superiority of the present arrangement, and to the credit of the Pacific coast be it said, that it remained for one of its engineers to design and successfully start into operation the first and only hydraulic sinking pump in the world. As it is from an original design by Mr. Moore, and not yet known as it deserves to be, I am informed that a thorough description of its main features will hereafter be given for publication.

It receives water under a pressure of one thousand pounds to the square inch, and when lowering the movable cranks are run towards the center, when the water is forced back into the accumulator and stored under pressure until ready for hoisting. By this means the moving mass when being lowered is made to store up power for the return trip, thus utilizing the power which in other hoists is wasted by the common hand brakes.

Big Hydraulic Mines.

The North Bloomfield and Milton hydraulic mining companies operating in Nevada county have made their financial statements for 1882. From them we gather these figures:

NORTH BLOOMFIELD.

Receipts.	
Gold bullion	\$386,146 23
Water sales	2,899 12
Dividends from branch companies	42,885 50
Personally reduced	4,059 80

Total receipts	\$436,000 65
Disbursements.	
Bonds redeemed, 106	\$106,000 00
Interest on bonds	37,075 49
Expenses of mining	153,714 03
Dividends	135,000 00

Total disbursements	\$431,789 52
Increase in cash assets	\$4,211 13
Showing net profit in working the North Bloomfield mine proper of \$235,331 32.	

MILTON.

Receipts.	
Gold bullion	\$416,044 17
Water sales	1,425 66
Personally reduced	11,759 05

Total receipts	\$429,228 88
Disbursements.	
Bonds redeemed, 50	\$50,000 00
Interest on bonds	12,818 83
Improvements on other property	12,908 07
Expenses of mining	236,592 53
Dividends	88,424 00

Total disbursements	\$400,743 40
Increase in cash assets	\$27,485 48

Showing net profit in working the Milton mines of \$180,877 30.

As these properties are among the leading hydraulic gravel mines in the State, the following tabular statement, showing their operations for the past six years, will be of interest:

	Bullion	Water
	Product.	Sales.
1877	\$670,774	\$ 6,754
1878	849,036	9,694
1879	794,518	9,091
1880	665,711	12,395
1881	637,682	24,433
1882	602,190	4,325
Totals	\$4,219,911	\$ 66,492
	Net profits.	Dividends
1877	\$ 364,045	\$ 45,000
1878	501,181	481,498
1879	462,821	422,640
1880	264,075	105,396
1881	325,227
1882	416,209	223,224
Totals	\$2,333,558	\$1,290,758

These mines were closed by injunctions for four months during the year 1881, which accounts for the small product of that year. At the beginning of 1877 the two companies were in debt over \$1,000,000. Since then this debt has been reduced to \$344,000. These payments and interest on this indebtedness chiefly account for the above discrepancy between profits and dividends.

MECHANICAL PROGRESS.

A Year's Metallurgical Progress.

The year 1882, says the *Ironmonger*, cannot be said to have been signalized by any single metallurgical discovery of a startling nature; still, it has not been an idle twelvemonths for our metallurgists. Nothing of a revolutionary character has been brought into existence, yet a good deal has been done in the way of economy and improved results under former conditions. Every succeeding year brings an enlargement of the means of production in all the principal manufacturing countries, so that the aggregate capacity of the world is growing at a rapid rate—probably faster, indeed, than the necessities of consumption require. With the augmented number and powers of the producers there is a natural growth of competition, which forces each individual manufacturer to adopt processes and economies which were not only unheard of, but quite unnecessary, a few years ago. The cost of production, therefore, is incessantly undergoing minimization, so that the selling rates of any former period afford no reliable criterion as to the profits of the time being. There is scarcely a single department of metallurgy which forms an exception to this general rule. It is especially true, however, of the iron trade proper, in which progress is the *sine qua non* of every manufacturer who wishes to hold his own.

Blast furnace practice furnishes a conspicuous illustration in support of this statement, seeing that by the construction of higher furnaces, the adoption of improved ovens for heating the blast and the utilization of the waste gases, the consumption of fuel has been immensely economized and the output much enlarged. This saving is being effected concurrently with a much larger output of pig iron.

The greatly enlarged make of special materials, such as ferromanganese or spiegel-eisen, is also noteworthy, especially when it is borne in mind that fixed percentages can be turned out with the utmost regularity and certainty. The efforts of our metallurgical chemists in this direction have been attended with so much success that we are not wholly independent of German supplies, but are doing a considerable export trade to the United States.

Direct processes of iron making are heard of more or less frequently, the latest claim in that respect being made on behalf of Mr. Bull; but we have not any tangible evidence as yet that the practice of that gentleman is likely to upset the existing methods of iron making, particularly as there can be no question that the so-called "direct" processes of Heaton and other inventors were in many respects meritorious and deserving of greater achievements than have been recorded in connection with them.

In regard to mechanical puddling, but little in the way of progress has been heard during the year. In Great Britain the human puddler is still a prime factor in iron making, but in this country both the mechanical and the human puddler seems in a fair way to lose their vocation, as experiments in Pittsburgh and Wheeling recently given in these columns seem to show, that nearly every grade of iron can be made by the converter. We condense from the *Ironmonger* as follows:

In rolling mill practice all the changes of the year seem to have been of a minor character. In this country experiments have been made for using alternate perpendicular and horizontal rolls, whereby it is claimed that loose rolls and the need for reversing is obviated.

As regards Bessemer working, it may be noted that the method of taking the metal direct from the blast furnace, to the converter, and thence to the rolls, is coming more in vogue. The soaking-pit process, introduced by Mr. Giers, has been very successfully worked at several places, and is likely to be extensively adopted, as being of the greatest utility in point of keeping the ingots sufficiently hot to permit of their rolled products turning out sound, the prices of the day rendering the avoidance of all intermediate processes a matter of stern necessity for all the rail makers. For general purposes Bessemer steel is apparently in constantly growing request, a result which is largely owing to the regularity and certainty with which the material can be obtained with any given percentage of carbon.

The Thomas and Gilchrist basic process has been more widely adopted in Europe, and, though skeptics yet doubt the success of the process, the evidence in its favor is overwhelming and there is no reasonable doubt of its future. Minor improvements are being made to this process, which are giving it increased value.

In all branches of the steel trade attention is being accorded to the effects of gases upon the materials, but the experts are not quite at one upon the subject, which is still under discussion by M. Pourcel, Dr. Muller, R. Snelus, Mr. Windsor Richards and other eminent men. There can be no doubt that the theme is most important, inasmuch as the causes which lead to the honeycombing of Bessemer ingots are, no doubt, similar to those which produce air-holes in ordinary iron and steel castings.

The method of tempering steel by means of enormous hydraulic pressure, suggested by M. Clemandot, a French scientist, has attracted much attention, and possesses certain features which will probably cause it to be more prominent shortly. Its especial merit seems to consist in the forcible expulsion of the gases, the

presence of which is generally admitted to be highly prejudicial to all metals.

Seguin, of Paris, has patented a process for increasing the tensional, torsional, etc., strength of iron by immersing it in hot dilute sulphuric or hydrochloric acid, but we have since heard little of the invention, and virtually know nothing in this country of its practical results. The utilization of tin-plate scrap has been spoken of in several quarters by means of oxidation and other processes, but the matter scarcely seems to have attained commercial proportions as yet. Blast-furnace slag is being more largely used for brick-making and other purposes, including the manufacture of glass and so-called wool. As regards the other metals, nothing of great moment has transpired.

An alleged discovery as to aluminum has been quite lately heard of from Birmingham, where it is said to have been in existence more than a year; but all that is claimed for the invention is not by any means admitted by those who have studied the matter. The problem of separating alumina from the oxygen with which it is combined has hitherto baffled the many clever chemists who have attempted to solve it; consequently the discovery made by Mr. Webster will prove of immense value if it equals the claims made on its behalf. In copper, tin, lead, spelter, etc., few alterations of note have taken place, albeit numerous minor improvements have been effected.

The hollow application of Bessemerizing to copper does not seem to have made so much noise in the world as had been expected by its advocates, but the separation to metals by electrolysis, as also electro-deposition, have steadily marched onward. Considerable progress has been made in respect of the working and applications of nickel. An English firm have produced malleable nickel and cobalt by adding a flux of metallic manganese to the fluid metal a few minutes before the casting.

The more exact and symmetrical testing of materials of all kinds has also been discussed of late on both sides of the Atlantic, and it seems probable that steps will sooner or later be taken to establish a system which shall be satisfactory at once to the manufacturer and to the inspecting engineer or contractor. At present many of the tests prescribed by the engineers are absurd, and inflict serious losses on manufacturers who honestly endeavor to supply a good article for the purpose indicated by the specifications submitted to them. Some day, perhaps, it may be found practicable to agree to standard tests for specific purposes, in substitution for the labyrinth of requirements now obtaining for precisely the same article.

Dispensing With Puddlers.

We have already made mention at length of the way puddlers are being dispensed with at the Wheeling rail factories by substituting mild Siemens steel instead of iron in the manufacture of nails. And now comes the Pittsburgh *Dispatch* with the following:

The experiments which are being conducted at Glenwood station in the manufacture of iron direct from ore are reported by those interested to have been attended with success. An eye-witness affirms that the newly patented Adams furnace is capable of making a heat of sponge ball ready for the muck rolls direct from the ore every hour. One charge that was timed was recorded by Mr. Wm. Pillow, an experienced iron worker, as having been "brought to nature," a term used by iron men, in 30 minutes, and in 10 minutes more was made ready for the muck rolls. The product when finished was pronounced by experienced puddlers who were present to be equal to the best puddled iron known as merchant bar. The furnace is a sort of combination of the Siemens rotary and the Purley furnaces, both of which were designed for the purpose of converting native ores directly into iron. They were each successful in a measure, but were found to be unwieldy and impracticable. The new process, if it continues to be successful, will seal the fate of puddling. The designer of the new furnace claims that he has a large number of orders for the new furnace, the validity of which will be based upon the result of the present experiments. Among those mentioned were Demmler Bros., who want 30 furnaces to do just the work which Mr. Adams claims his furnace will do. "It would be a novel sight," said a witness of yesterday's operations, "to see a train load of ore come into a mill and go away in an hour afterward in the shape of bar of iron in the same cars."

WOOD VS. IRON IN FIRE.—The London *Telegraph*, speaking of the recent great fire in that city, says: "It is of interest to notice the effects of intense heat like this on different constructive substances. There has been a tendency of late years to trust to iron; but yesterday's test was altogether unfavorable to this substitute for wood. An experienced officer of the fire brigade remarked: 'Whenever we know there are iron girders and pillars we give them a wide berth. They expand so much that you can never be certain of them. Take a floor resting on wooden beams, say 12 inches by 8. It will burn for hours without giving way, and will not swell at all, and not displace any part near it. Not so with iron; it soon becomes red-hot, expands with terrible force, and, as I think, does more harm than good.' This view was confirmed by the fact that buildings like the Curriers' hall, the rear walls of which were subjected to a terrible scorching, escaped with little damage, while in no case did an iron partition seem to be of avail."

SCIENTIFIC PROGRESS.

What The Telescope has Done for Astronomy.

The foundations of physical astronomy were laid in the invention of the telescope. Everyone has heard of the emotion which filled Europe at the announcement of the discovery of an instrument which had the power of making distant objects appear as if they were near. It was at that time that Galileo, having only learned that such an instrument existed, discovered its arrangement, constructed one, turned it toward the sky, and, with this aid, fertilized by his genius, made a series of magnificent discoveries. These discoveries belong pre-eminently to physical astronomy, and form its first courses. If we except the sun and moon, which have a very sensible diameter, and admit of some observations without the aid of the telescope, all the stars appear to the eye only as brilliant points, and admit of no studies except of their motions. Therefore, an astronomy without the telescope would never have permitted us otherwise than as a matter of probability to consider the planets as like the earth in form, constitution and office. But when it was seen that these brilliant and almost blazing points were resolved under the telescope into well-defined disks, showing indications of continents, clouds and atmospheres, when satellites were perceived around those globes playing the same part to them as the moon plays to the earth—then probabilities gave place to a clear certainty. Telescopes, then, are the instruments by means of which the constitution of the solar system has been definitely unveiled, and the earth has been assigned its part and its rank in the system of planets. The discovery of the spots on the sun and of its rotation completed the conception of the solar systems and prepared for the theory of its formation. Here is marked a well-determined phase in the history of human ideas respecting the universe, and it is characterized by the great name of Galileo.

Was it possible at once to go beyond this? Was it possible to question the stars in their turn, and inquire if, like the sun, they had a sensible disk, spots, a rotation, and planets revolving around them; was it possible, in short, to extend to the stellar universe the notions we had already acquired concerning the solar system? The methods in use did not yet permit this.—*Popular Science Monthly*.

The Luminosity of Flame.

Considerable discussion has been indulged in with regard to the cause of the luminosity of flames, and still the question is far from a settlement in which scientists can generally concur. The editor of the *Machinist and Builder*, assuming that the luminosity in question has reference more particularly to luminous hydro-carbon flames, of which the flame of the candle or of burning gas is the representative, remarks that though there is still some question concerning it, the weight of opinion is decidedly in favor of the view that the luminosity of such flames is caused by solid incandescent particles of carbon. This is the old theory, which was accepted for years without question, until Frankland challenged its correctness and endeavored to prove that the light-emitting material of such flames was highly heated vapors of more or less density.

The whole subject, however, has lately been reviewed by Henmann, who reaches the conclusion that the old explanation is the correct one. With this conclusion we fully agree. The proofs which Henmann offers are: 1st. The increased luminosity which chlorine imparts to weakly luminous or non-luminous hydro-carbon flames, which is due to its well-known property of separating the carbon as such. 2d. A rod held in a flame is smoked on the lower side only—that is, the side opposed to the issuing gases; were the carbon there in the form of vapor, as Frankland assumes, it should be condensed by the cooling action of the rod and deposited uniformly all around it. 3d. A body held in flame is smoked, even when it is in a state of ignition; this therefore cannot be explained by a condensation of vapor. 4th. The carbon particles can be actually seen in the flame when it is made to strike against a second flame, or an ignited surface, the carbon particles aggregating together to form visible masses. 5th. The luminous portion of a flame is not very transparent—no more so than the layer of smoke of the same thickness which rises above a flame fed with turpentine. And 6th. Flames which unquestionably owe their luminosity to the presence of solid particles, give a shadow with sunlight, precisely as do hydro-carbon flames; while luminous flames composed of ignited gases and vapors only, give no such shadow in sunlight.

THE SUN'S DISTANCE.—Calculations, based upon the several observations taken during the last two transits of Venus, have nearly, if not quite all, resulted in reducing distance which has been supposed to exist between the earth and the sun. Our works on astronomy formerly made the distance about 95,000,000 of miles. Most of the estimates eight years ago made it about 93,000,000. Approximate figures from the last transit have reduced the distance to less than 91,000,000.

Chemistry of the Electrical Accumulators.

With the attention that is now directed to the storage of electricity, the following description of the chemical action of the Plante and Faure accumulator as given in a German exchange will not be without interest:

If a plate of lead, coated with a little peroxide of lead, be placed in sulphuric acid, it will soon become covered with sulphate of lead as a result of local currents between the peroxide and the lead, or by simple chemical solution, so that in Plante and Faure's battery the peroxide is gradually destroyed *independently* of the main current. This action takes place very slowly, because the sulphate of lead is deposited between the lead and the peroxide, and hence greatly diminishes the local current. If no sulphate of lead were formed, the peroxide of lead would soon be all consumed. The sulphate of lead is subsequently reduced by the hydrogen, forming spongy lead. By repeated charging, the quantity of finely divided substance increases.

In a similar manner, if two electrodes that are covered with sulphate of lead be immersed in dilute sulphuric acid and a current passed through them, one will become covered with spongy lead, the other with peroxide formed from the sulphate.

The peroxide formed upon the positive lead plate of the secondary battery becomes covered with a comparatively impenetrable layer which prevents the further production of peroxide; hence Plante leaves his battery at rest, which favors this formation of sulphate of lead.

In this way all the sulphuric acid can easily be taken out of the solution. A considerable quantity of oxygen—more than half—will not be absorbed. According to Kabath, the interior plates of lead foil are rapidly crumbled, but the particles remain hanging between the outer plates.

ELECTRICAL PROGRESS.—Scarce a month goes by without some important advance in electricity in some one or more of the various purposes to which it is applied. Now it is the telephone that is improved; next the dynamo machine; then the electric light, and again the storage battery, and so on. A late correspondent of the *New York Letter* says: "In the office of the scientific expert, Park Benjamin, I saw yesterday an invention which may be the electrical sensation of 1883—a cheap battery, which, for small motors fit for sewing machines, lathes, etc., surpasses our present cell batteries as 50 to 1. Every person dealing with electricity knows the Grenet battery, a bottle containing a solution of bichromate of potash and sulphuric acid, into which are plunged a piece of carbon and a piece of zinc. The electric current produced is strong, but at the end of 24 hours the solution has lost its strength and has to be replaced. For this reason the Grenet battery is only used when a current is needed for a few moments; the zinc is so arranged that it can be plunged into the liquid and lifted out again by working a small rod. Mr. J. M. Stebbing, of this city, patented last year a modification of the Grenet cell, in which, by the simple introduction of a dividing plate of porous material, the solution remains unimpaired and the battery goes on working for six months, or until the zinc is consumed, instead of giving out at the end of 24 hours. Tcs's have been made by different experts with the batteries, and they have fulfilled all that the inventor claims for them. A company has been formed for their manufacture and sale, and they will be put upon the market very shortly. Each cell occupies about the space of a hat box. Four cells will run a sewing machine, and six will run an incandescent lamp; the cost for each cell will be about three cents a month. Experts say that if half of what is claimed can be done, there will be no more use for dynamo machines or storage batteries."

ELECTRO FLUID AND FIRE BATTERIES.—We have already noticed in these columns the electro fuel and fire batteries of Dr. Brand. That gentleman is still prosecuting his researches in this direction. His latest production is reported to be a torch or candle, which in burning produces an electric current. As described by *Engineering*, of London, England, it is made by compressing a paste of coal dust and treacle in a mold along with two wires which issue from one end and serve as the negative electrode. The stick thus obtained is wrapped in a thin sheet of asbestos paper covered with copper wire to serve as the positive electrode. The core is then dropped into a bath of fused nitrate of potash until a layer from .2 to .25 inch thick adheres to it. In the candle thus obtained the carbonaceous agglomerate forms the wick and the nitrate takes the place of the wax or tallow. On setting fire to the wick it continues to burn, and on connecting the wires to a galvanometer a current will be observed during the whole time of combustion. This current is not very regular, however, owing to a crust of nitrate and to the resistance offered by the wires. It is stated that ashes mixed with the nitrate, in the proportion of two parts of ash to one of the salt, cause the candle to burn more regularly, and to give off a remarkably steady current.

FORTY-NINE electric light companies, with \$81,390,000 capital, were set agoing in Great Britain last year.

MINING SUMMARY.

THE Noonday, North Noonday and Red Cloud mining companies, Bodie, have gone into voluntary insolvency. The Court below found general orders staying proceedings against them; also special orders directing the Sheriff at Bodie to proceed no further in execution against them.

MANMOTH.—*Ledger*, Feb. 3: This quartz claim, formerly known as the Spanish gulch mine, is located on the ridge between Murphy's gulch and the Mokelumne river, about half a mile from Middle Bar and 3½ miles south of Jackson. It is at present entirely owned and worked by W. A. Nevills, who, for 5 or 6 years past, has done considerable prospecting in this section of Amador county. In the Mammoth lead the indications are that the richest bonanza ever discovered in the county has been encountered. Mr. Nevills has been quietly working with a small force of men since September last, and from the very start a stroke of good fortune has attended his operations, never realized by any one man in these parts of recent years. About 2 years ago the mine was bonded to Mr. Nash for a short term, who, after prospecting on a limited scale, without any flattering result, surrendered the property to its owner. The point where Mr. Nash quit was only a few feet from a continuous stream of solid gold, which has been followed in the working of the regular ledge for some 200 ft, and still shows no signs of petering. Last Wednesday we visited the property and were shown over the ground by Mr. Nevills himself, and what we saw fully satisfied us that the reports of the unexampled richness of the ore are not only realized, but eclipsed by the actual facts. The shaft is somewhat over 100 ft deep, and located about 600 ft from the northern limit of the claim. From this shaft two drifts have been run, one south and the other north. It is in the latter that the golden harvest, which has already made the mine famous, has been reaped. This tunnel is now in about 200 ft, and the ledge matter at the face shows 20 ft in width. Whilst the whole of this shaft ledge is of high grade rock, the chert is

free gold are taken from a small seam resting on the foot-wall. This seam varies in thickness, sometimes narrowing to the dimensions of a knife blade, and then widening out to 6 or 7 inches. Where this widening occurs as much as \$2,000 in free gold has been blown out by a single blast. The quartz is frequently held together by spikes of gold. We have shown a couple of pans of ore from this seam. Many of the specimens would assay in the hundreds, and the value of the two pans would reach into the thousands. The rich foot-wall streak is not followed separately, but only worked in connection and as a part of the main ledge. When in the process of blasting the gold vein is displaced, the fragments are sacked and sent to the surface, and in this manner alone the large amount of free gold has been extracted. Several hundreds of tons of rock from the main ledge lies on the dump. Experts estimate that the whole of the pile will yield \$40 per ton. It carries enormous quantities of sulphurets. Samples of ore casually picked from the dump showed free gold in several instances. A fine 30-horse power engine is used for hoisting purposes. The 10-stamp mill is being rapidly put in running order. At the time of our visit carpenters were at work putting in bidders for saving the sulphurets. The rock carries too heavy a percentage of sulphurets for the Frue concentrators to clean up. From the looks of the rock we should judge that 75 to 20 per cent. of the dump pile is sulphurets. The mill is expected to be running inside of a month. From 10 to 12 men are employed at present, but this force will be increased when the mill gets to work. Some idea of the bonanza may be gained when we say that so far, whenever Nevills has needed a \$1,000 or so to pay his hands, he has spread some of the rich ore on a piece of sheet iron, built a fierce fire under it, and the pure metal has flowed out sufficient for all requirements. This splendid strike can hardly fail to give an impetus to prospecting through the entire region between the Moore mine and Middle Bar.

CALAVERAS.

CARSON HILL.—*Mountain Echo*, Feb. 3: We learn that the entire mining property belonging to Gabriel Stevenot, situated on and near Carson Hill, was recently sold to a San Francisco company for the sum of \$150,000. It is also said the company will soon commence work. A clean-up was made last week from 4 tons of ore which was taken from the Invincible, and which yielded about 50 per ton. The shaft is 80 ft deep, and the vein is over 7 ft wide. Messrs. Reed & Co. are rapidly developing a valuable mine.

INYO.
THE DEFIANCE FURNACE.—*Independent*, Feb. 3.
The Defiance furnace, at Darwin, J. S. Gorman, superintendent, closed down on the 27th ult. for a few weeks, during which time Mr. Gorman will pay a visit to the Bay. The furnace has been in blast only at intervals since January a year ago, but has produced a total of 340 tons of bullion, of the assay value of 145 ozs silver and 57 in gold per ton. The lead averaged a value of \$95 per ton. Work will be resumed about the 1st of March. In order to advantageously extract the body of ore in the south workings of the Defiance mine, a new shaft will have to be sunk, else a drift be run 400 ft southward, which remains to be determined.

THE MODOCK.—Supt. Fitzgerald has just refitted the Modock furnace, at Lookout, with a new water jacket of the latest pattern, and in a few days will start up for a long run.

PROSPECTING.—J. H. Stoutenborough, W. A. Bollinger and Bart McGee, of Bishop creek, are prospecting in Deep Spring district.

NEW MILL.—The machinery for Lasky's new mill, at Arastra canyon, Beveridge district, is being packed over the Inyos from Lone Pine.

SNOW'S CANYON.—Eddy, Waterman & Co. will this coming week start up their mill, at Snow's canyon, on a lot of fine ore that will keep it busy about 25 days. Stapp & Morton have out about 40 tons of ore that assays \$200 gold and \$120 in silver.

FOUND SOMETHING.—Gould & Jackson have found a 2-ft ledge of ore in their Gypsy Queen mine, at Darwin. The ore goes 72 ozs silver and 55 gold per ton. They will put up a whim that will enable them to sink at least 200 ft.

AT BISHOP.—Our correspondent, at Bishop creek, says that public interest there now centers on the Sacramento mine. Supt. C. L. Van Epps says the new 5-stamp mill will be in operation by the 20th inst. About 200 tons of ore are already extracted, and a force of men is employed at the mine.

MINING SALE.—A half interest in the Wild Rose mine, in Clover Patch district, near Benton, has changed hands for \$30,000.

MARIPOSA.
BONDED.—*Mariposa Gazette*, Feb. 3 The Eureka, known as the Quartz Mountain mine, and property of the Washington Mining Company, has been bonded to Moses L. Rogers for \$9,000. This is good evidence that the rock of Quartz Mountain mine is good, and will not be abandoned, as was feared by some.

SILVER MINE ENTERPRISE.—It is reported that Mr. Leavenworth, superintendent of the Silver mine, will shortly commence laying 2 miles of 1½ inch iron pipe to bring in water sufficient to run the mill steady.

THE CHRISTMAS GIFT MINE.—This mine, situated 10 miles from Mariposa and 1 mile from Cathay's valley, has a finely developed true 6½ ft vein, averaging from 12 to 18 inches in width. They have a 5-stamp mill.

NEVADA.
THE DERBEI TUNNEL.—*Nevada Transcript*: The new drain tunnel of the Derbec mine is in 2,300 ft, and within 500 ft of the new shaft, which it will reach during the next 80 days. The gravel in the tunnel is looking well, the whole breast being in it. Good pay is being taken from the old shaft. About 65 men are employed by the company.

GOOD ROCK.—*Nevada Herald*: The New Year quartz ledge, situated on Deer creek, above the old Leocompton mine, and about 3 miles from this city, is looking very well at present. A vein of ore 1 ft in width was uncovered a few days ago, and it is estimated that the rock will yield between \$30 and \$40 per ton. The mine is being worked through a tunnel that has been driven some distance into the hill, and the indications are that the body of rich quartz just encountered will prove quite extensive.

PLACER.
HOTELING ITEMS.—*Placer Argus*, Feb. 3: A gang of 12 or 15 carpenters are at work on the new buildings of the California Iron and Steel Company, at Hotelling, to replace those burned on the 10th of September last. The new buildings will have a framework of timbers with the sides and roof of corrugated iron, thus making them less liable to destruction by fire. Six carloads of fire-proof brick lately arrived from Pittsburgh, Pa., to be used in lining the furnace. It is thought with these and other improvements the new concern, when it begins operations—about the middle of April it is hoped—will be able to turn out 30 tons of iron per day. Enough wood had already been cut before the fire occurred to supply the kilns for the coming season.

DECLINED.—The Pearson and Hawken boys, owners of the Morning Star quartz mine, near Ophir, declined an offer of \$40,000 for their mine last week. They ask \$60,000 for it.

MICHIGAN BLUFF AND VICINITY.—We have had a little rain during the past week, but not enough to do the miners any good. The Hidden Treasure mine, which has been shut down for a week or so days past to permit of certain necessary work in the way of repairs and refitting, is now about to start up again with its usual force of 65 or 70 hands. The repairs have been going on for 3 or 4 months past. A new dump has been constructed, some miles of heavy new T rails have been laid, together with various other improvements too numerous to mention. The company is now prepared to go on with work in real earnest.

PLUMAS.
CRESCENT MINE.—*Greenview Bulletin*, Feb. 3: Since our last issue the water in the shaft has been pumped out down to the second level. By the end of the week Mr. Davis thinks this level will be sufficiently drained to allow him to put men to work, when he will start to crosscut for the 4 ledges now exposed at the surface. This shaft was originally put down on what was known as the Pet ledge. It goes perpendicular to a depth of 200 ft; then there is an incline of 75 ft. From the top of this incline the shaft will be sunk perpendicular an additional 300 ft, and crosscuts will be run at convenient distances in the shaft to tap all the other ledges. In this Pet ledge Mr. Davis is quite confident of finding a large amount of rich rock. In fact, he says he knows exactly where there is a large ore body that was in sight when the mine was closed down years ago, and that will yield better than any ore that has been worked since the mine was started up this last time.

ROUND VALLEY WATER COMPANY.—The late rain raised the reservoir a little, but is now about where it was before the storm. However, even though the overflowed area is constantly being lessened, the water is not falling as fast as during the cold weather, showing that the inflow is almost sufficient to supply the demand. It is hoped, at all events, that at least a portion of the Green mountain mills can be kept running. With the present alternating condition of weather, we may, at almost any moment, have storms that will set aside all danger of delay in the running of the mills. Mr. Bidwell, the superintendent, has just completed a "loop" of about 1,000 ft of wire, connecting the ditch-tender's cabin with the telephone system. The superior advantages of this arrangement are at once apparent. As in case of any accident to the ditch or variation in the water supply, communication can at once be had either with Green mountain or Indian valley, or word or assistance sent from town.

TAYLOR-PLUMAS MINE.—The new mill is running splendidly, every part of the machinery working to perfection. During the past 4 days the stamps have been kept at a speed of 72 drops per minute. The flumes, ditches and pipe are in complete order. In a word, the whole mill and attachments are working like a charm. In the mine the winze is going down rapidly, and the ledge grows larger as depth is attained. The ore appears also to improve in quality in the stopes which are just being opened.

SAN BERNARDINO.
BURNING MOSCOW.—*Calico Print*, Feb. 3: Work is progressing on this mine. Eighty tons of ore have just been crushed at Sherman's mill, and 5 or 6 tons are being taken out daily, which are carried down to the wagons on donkeys. This mine is showing up better than ever. The main shaft is down 140 ft, and a tunnel is run roof.

SILVER ODESSA.—The lumber has arrived for the chute to be built at the Silver Odessa mine, and work has been commenced by several carpenters, under the supervision of Pete Kleine.

GRANITE DISTRICT.—Mr. Morrow, from the

Granite district, paid our office a visit the other day. He reported everything flourishing in that district. Work is being performed on some of the mines, which show up well. Some of the shafts are down 40 ft. The El Capitan is one of the finest ledges there, in which Mr. Morrow and W. N. Joiner, of this place, are interested. About the 5th of next month Mr. Joiner is going out there to work on the same. Mr. J. W. Bailey, of San Bernardino, has also struck a fine ledge and feels elated over his good fortune.

GODFREYVILLE.—The boom has at last come to our little burg. The first settlers here did not have to wait as long for it as they expected. The Silver Odessa mining company is building a good road and putting in an ore bin, turn table, etc. They have built a good, comfortable bunk house for their men. The boarding house is now built, and expects to be ready to commence business in a very short time. All the boys in the camp are at work. That is what all mining camps need to insure its success. There is work for all here that will work, and we have no use for bums. Mr. Raymond's mines are now looking fine. All his men are at work on ore. He is sinking a shaft on the Garfield, and in the bottom he has struck a small seam of ore that is almost solid silver. The Evans Bros. are getting some fine ore from Dragon No. 1. That mine is yet destined to be one of the foremost mines in Calico district. The Alhambra is now looking fine. There are two men at work sinking a shaft, and they are getting good ore.

SHASTA.
PLUMBAGO.—*Shasta Courier*, Feb. 3: Several years ago L. Eller discovered a mine, or heavy deposit of plumbago, about a mile from his place, and since then he has prospected it enough to satisfy himself that there is a great quantity of that substance in the location.

SIERRA.
REPAIRS.—*Mountain Messenger*, Feb. 3: Jack Jones, from Little Grizzly, informs us that the company has completed its repairs and will soon be taking out pay again. The prospects are very favorable for continued prosperity. The claim is without doubt one of the best in the county. . . . Mr. Shaw, a large holder of stock in the Marguerite quartz mine at Loganville, has arrived from Boston and taken charge of the business of the mine as superintendent. The mill is running on good rock, and the prospects of the mine were never better.

TUOLUMNE.
PATTERSON.—*Tuolumne Independent*, Feb. 3: The new shaft on the Patterson mine has reached a depth of over 500 ft, and free gold comes up to the surface in every bucket. The company is about to add 10 more stamps, making 30 in all. With good management, Supt. Drake keeps the mill well supplied with 5 men.

RAPAHANNOCK.—Work is being resumed on this mine, which is an extension of the Rawhide mine. The machinery is being repaired preparatory to pumping out the old diggings. . . . Divoll has leased the Keith pocket mine at Jacksonville. The thing is worked with an open cut. . . . Captain Colby has struck another rich pocket at the Big Nugget claim. . . . The Buchanan mine will be opened and worked on a larger scale than heretofore.

Nevada.

WASHOE DISTRICT.
MEXICAN.—*Enterprise*, Feb. 3: On the 2900 level the joint Union Con. east crosscut is making good progress in a formation containing many metal bearing feeders and stringers of quartz. At the joint Ophir winze, down from the 2900 level, guides are being put in for a second line of cages. The guides will all be in and the cages running in about a week, when a crosscut will be started east from the station at the 3100 level.

HALE & NORCROSS.—The north drift on the 2600 level, joint with the Savage, is being advanced at the rate of about 40 ft per week. The drift is still cutting seams and feeders of ore that assay well. Once the drift has been carried through to the Savage line work will be done for the prospecting of the most favorable among the streaks of ore cut across.

SIERRA NEVADA.—The crosscut on the 2700 level is still following the vein of quartz which leads out to the east. The north lateral drift on the 2900 level is making about 20 ft per week, and the east crosscut on that level, joint with the Union Con. Co., is being advanced at about the same rate of speed. Both are in vein material.

UNION CON.—The joint Sierra Nevada east crosscut on the 2900 level is making about 20 ft per week in a promising vein formation. The east crosscut, joint with Mexico, on the 2900 level, is still cutting many feeders of quartz, all of which carry more or less metal. The ground from the 2700 level down is now pretty well dried out.

OPHIR.—The cages will be running in the second compartment in about a week, when a crosscut will be started east from the station at the 3100 level. On the 1600 level are repairing the drain tunnel from the main incline to the Suto tunnel north lateral drift.

SAVAGE.—The north drift on the 2600 level, joint with Hale & Norcross, is making good progress in ground that shows some small feeders of ore. It has yet a considerable distance to go to reach the south line of the Savage ground.

UNION SHAFT.—The pump-roads are all in, and the new pumps will be in place and running by the middle of next week. Some repairs are being made to the drift on the 1600 level, which leads out to the north branch of the Suto tunnel.

NORTH GOULD & CURRY.—The bottom on the shaft is in porphyry containing some seams of quartz and clay. Another shift of 5 men will be put on the first of next week, and sinking will be pushed as rapidly as possible.

GOULD & CURRY.—The west crosscut of the 2500 level is in a reef of hard blasting porphyry. It is likely that a favorable change will be seen when this hard belt has been cut through.

CROWN POINT.—All work on the old upper levels is going on as usual, and the usual amount of low-grade ore is being extracted and shipped to mills on the Carson river.

YELLOW JACKET.—About the usual amount of ore is being extracted and shipped to the mills. The exploring drifts are still finding occasional bunches of paying ore.

BRISTOL DISTRICT.

CLOSED DOWN.—*Pioche Record*, Feb. 3: The mill of the Bristol S. M. Co., which has been running on tailings for a short while, closed down last Saturday, owing to the cold weather. Then, again, there are not many tailings at the mill. A few checks, given by the Bristol S. M. Co. to employees for labor, about a month ago, drawn on Mr. Welles, have been protested in the East. These checks were given to men who refused to file liens on the property of the company. All the men who filed liens received their pay, while those who, to favor the company, refused to file liens, have not been paid, and as the time of limitation has passed, the chances are that they never will be. Men are very foolish to take such risks for their pay, when it is wholly unnecessary.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, Feb. 3: The main winze from the fifth shaft level is down 124 ft on an incline, which is equivalent to 100 ft perpendicular. A drift has been started from the bottom of this winze, and runs toward where the shaft will be when sunk to that depth. The stope above the first shaft level shows the usual length and width of ore, but it is not so fine in quality, being mixed with streaks of slate, requiring considerable sorting. The other shaft levels present no change. The appearance of the adit and levels above is much the same as last week. The development on the ninth has been opened a length of 30 ft, and shows a vein of very fair grade ore 3½ ft in width. The daily output of ore is about 60 tons, which mill No. 2 continues to handle well, running smoothly meanwhile. A total shipment of bullion amounting to \$66,173.61 was made during the month of January, with one more shipment to be made on that month's account.

MOUNT DIABLO.—The stope above the drift connecting winzes Nos. 1 and 2, shows a foot of \$75 ore. A wide ledge has been encountered in winze No. 2, having 15 inches of ore assaying \$80 per ton, besides several smaller streaks of good grade ore. The intermediate drift below the third level, and west of winze No. 1, is giving some \$60 ore from bunches in a wide ledge, from which the assays average \$45 per ton. The stope above winze No. 4 shows some 20 inches of \$75 ore. Several carloads of \$60 ore are being extracted daily from the stope above the west drift from the Callison winze. Considerable ore of the value of \$70 per ton is being taken from the intermediate, below the first level, at various points. The stope from the west drift, from the south crosscut in the eastern part of the first level, shows 15 inches of \$90 ore. The Tipton ledge still continues to yield a small amount of \$70 ore.

COMET DISTRICT.

BEGINNING TO BOOM.—*Pioche Record*, Feb. 3: Comet district is beginning to boom. All the prospectors from Bristol district are there. There are now several very excellent prospects uncovered. A large number of people have visited the district during the week, and all are unanimous in pronouncing it an exceedingly big showing for on the surface. The owners of the claims have just commenced to work them, and, of course, have great expectations, which we hope will be realized.

EUREKA DISTRICT.

HAMBURG.—*Eureka Sentinel*, Feb. 1: From J. C. Powell, superintendent, we learn that the strike reported in the Hamburg mine is a body of rich ore about 18 inches wide and some 4 ft, running crosswise of the face of the drift about 45 degrees. At both ends it seems to spread, making down and up. The extent of the deposit cannot be determined for several days yet, as a large body of low-grade ore has to be cleared away before the work of development can be pushed. Mr. Powell thinks it will prove similar to other small chambers of high-grade ore that have been found in the mine. There are about 200 tons of low-grade ore knocked down. In about a month the engine will be put up, and this ore, with what more may be dug out in the meanwhile, will be hoisted out and shipped for reduction. Mr. Powell tells us that a very nice find has been made in the Silver Lick also. In the face of a 60-ft drift, run from the bottom of the 60-ft shaft, the entire face of the drift is in ore that will go from \$60 to \$80 per ton.

JACKRABBIT DISTRICT.

WORKING.—*Pioche Record*, Feb. 3: Many of the claim-owners of Jackrabbit district are industriously working their claims, and many of the prospects exhibit good ore. Most of the work being done in the Day mine at the present time is done by contract.

REBEL CREEK DISTRICT.

MILLING AND MINING NOTES.—*Cor. Silver State*, Feb. 3: In consequence of the severe cold weather experienced here during the past two or three weeks, the new mill of Messrs. Harlan & McColley has not attempted to make a run. The roads from the mines to the mill are mostly as nature made them, and nature having furnished them with a liberal coating of ice and snow, the hauling of quartz is a matter attended with much difficulty. The danger of bursting water pipes, and the liability of ditches giving way during extreme cold weather, are doubtless some of the reasons why the commencement of hostilities has been so long delayed. Everything is now ready, and all hands hope for an early start and successful run. For what it is worth, I give you my opinion of this, Rebel Creek district. There are running through this district, four separate and distinct mineral belts, or formations. The first and lowest on the foothills is silver-bearing, with copper predominating as the base metal. The second bears both gold and silver, with iron predominating as the base metal. The next is silver, with lead for the base, and last, but not least, a free gold formation. I am not sufficiently versed, either practically or theoretically, to know whether this arrangement will stand a scientific test. This is a large district, and but slightly prospected. With some experience in mining camps—tough experience, by the way—I do not hesitate to say that I know of no locality so desirable or promising for the prospector or capitalist as this, and no time so good as the near future.

TAYLOR DISTRICT.

MILL.—*Pioche Record*, Feb. 3: Dick Milliek reports that the Taylor mill, in Taylor district, is to have an addition of 15 more stamps, and be started up as soon as the cold weather abates.

SPRING VALLEY DISTRICT.

EAGLE MILL.—*Silver State*, Feb. 3: The Eagle mill, in Spring Valley, south of Unionville, is now running steadily on ore from the Eagle mine. The property is owned by the Vandewater company, and is managed by Major E. D. Luxton. A fine body of rich, gold-bearing quartz has been opened in the mine at a depth of 160 ft from the surface, and it is said to be paying handsomely. Below the mine some 60 Chinamen are at work placer mining. These placers have been worked for several years, and have produced over a million dollars worth of gold dust. It is generally believed by miners that there are several rich gold leads in the mountains above the placer mines, as very rich float quartz has been found on the surface, and that sooner or later those leads, of which the Eagle is one, will be worked extensively.

WARD DISTRICT.

BULLION.—*Pioche Record*, Feb. 3: Nine bars of bullion was shipped from Ward last Thursday morning. The mine of the Martin White company is of greater value than the public have any idea. Gilmer & Salisbury intend putting on four-horse coaches from Ward to Eureka.

Arizona.

MINERAL HILL.—*Pinal Drill*, Feb. 3: Mr. Thorning has returned from the Bruiser, situated in Box Canyon, in the range of mountains generally called Mineral Hill district. A very large body of argentiferous galena appears disclosed by the last work, giving assurance of an immense ore-body and a very valuable mine.

LOWER TURKEY CREEK.—*Cor. Prescott Courier*: The mining outlook was never brighter than it is at present in this section. Smelting furnaces and sawmills are going up in the different parts of the district. The mines are looking well and turning out plenty of ore. The following is a description of some of the mines:

MOUNTAIN VIEW.—This fine property is situated a mile and a half below the old Bully Bueno mill, on the east side of Turkey creek. In this claim are two strong veins, some 50 ft apart, the average width of each vein is over 4 ft. The ore is a fine galena, assaying from \$50 to \$125 per ton, silver. The ledges run north and south. On the east vein the shaft is down 50 ft, and drifts are being run from the bottom. The company will sink their shafts 300 ft, drifting every 50 ft. The shaft on the west vein is down over 50 ft, showing a fine body of ore. Assays from the croppings of this vein averaged \$250 per ton, silver. There are at present over 200 tons of good ore on the dump of this mine. This company own also, the Red Cloud and Howland mines, south extensions of this mountain vein.

Colorado.

LA PLATA DISTRICT.—*Cor. Rocky Mountain Mining Review*, Feb. 3: The first mining claim staked in Clear Creek camp was in the fall of 1880. The writer was one of the number who packed his burro and started, and we found what we then thought would turn out big, and have not been disappointed. The progress of the camp from that time to the present has been slow and steady, but sure. Hundreds were in last summer, and many rich finds were made. The Fortune mine, one of the first discoveries, was bonded a few days since for \$75,000. Two shifts of men are now at work taking out ore valued at from \$200 to \$600 per ton. This property is situated quite near the town of Winfield. Wm. Wallace, discoverer of the Hesperus mine, last September, has been steadily shipping ore from the surface, receiving for each carload \$3,000 net. The Swiss Boy is a valuable mine, steadily shipping ore of a high grade. The Mammoth mine is among the biggest. It has been in litigation for some time, but now the matter is settled. Messrs. Cunningham & Co. have possession, and are erecting concentrating works with a 65-horse power boiler. This mine has an immense body of ore, the vein being 4 ft wide.

New Mexico.

TELEGRAPH.—*New Southwest*, Feb. 1: The developments in the Telegraph district show richer and larger ore bodies as greater depth is attained.

SMEILER.—John R. Magruder has made arrangements to erect a 30-ton smelter in the Hanover gulch. It will be built entirely for the purpose of doing custom work.

IN SIGHT.—The St. Louis and other mines of the Valverde Co. shows a great many thousands tons of ore in sight ready for stopping. These mines alone can furnish forty tons of freight per day to the Silver City and Clifton railroad.

Oregon.

NOTES.—*Jacksonville Times*, Feb. 3: Miners favored with good water rights are at work. Miners in Josephine county have a good supply of water and are busy. More rain has fallen there than here. Miners in the northern portion of Jackson and Josephine counties have plenty of water and are using it to good advantage. The party working Bybee & Saunders' claim on Rogue river, Josephine county, have struck good prospects and are doing first-rate. Both of the quartz mills at Horsehead and Blackwell are now in the best running order and good reports may be expected from them. Considerable ore is being taken out. J. E. Gale and E. E. Moore, who are mining at Hole-in-the-Ground, Leland precinct, are getting good prospects. They picked up a piece of gold worth \$8, the other day. The Sterling mine has not been able to do much this season, owing to the cold weather. Mulkey & Co., who are mining A. P. Talent's land on Wagner creek, have an abundance of water and are doing well. They washed a rod of dirt not long since and obtained over \$100. We were shown some excellent prospects from that claim this week. Judge Hanna has directed the superintendent of the Wimer & Simmons mine near Waldo to work only the undisputed ground. Mr. Hansen has given the required bonds and operations are progressing with dispatch since the cold spell was broken. There has been some rain during the past week, but not enough to give most of the miners a sufficient head of water. Still, there is every prospect of a good run yet, as the cold snap seems to be over and but little more rain is necessary to start a plentiful supply of water.

LIVER diseases, headache and consumption, caused by bad digestion, quickly cured by Brown's Iron Bitters.

Eastern Utah.

The Mining Camps Amid the Peaks of Uintah.

A correspondent of the Salt Lake Tribune, writing from Brown's Park, says: Brown's Park and vicinity contain much that is of interest in the line of minerals and physical features. We shall be disposed to refer to it again. From Brown's Park postoffice the traveler crosses the river and wends his way over a plat of some two miles in extent, where he enters a thick growth of cedars, and the ascent of the main range of the Uintah's begins in earnest. Up a rough rocky hill for a mile through the thick cedars the road bends to the left and goes down into Trail creek canyon, up which the road runs. This is a very rough, bad road.

Somewhere about two years ago the Green river folks got an unusual streak of enterprise, and raised about \$2,200 to work the road from Green river to Thornburg, but some contention arose as to the manner of disbursing the funds when the work was in progress, and operations ceased, the result being that the road is spasmodically good for a short distance, and shows off to advantage the naturally bad places. This particularly bad portion is, however, only about seven miles long. When the ascent is made, a very pleasing country greets the traveler.

It is composed of high and rough peaks, with smooth and comparatively level valleys, the mountainous portion being covered with cedars, and the valleys with a heavy growth of rich grass, and an occasional spring or brook. As may be supposed, this is an excellent summer range for stock.

Through passes and valleys we take our way to the west by south to our destination. For about 15 miles we pass through a formation of old red sandstone, and wonder at the immense mountain. We may add that this is the general characteristic of the northern slope of these mountains, which extend for a distance of over 100 miles in length. Near the watershed of these mountains the formation suddenly changes to that of the carboniferous age, the contact between the two periods being strongly marked and the change abrupt. Now we see quartzite and the old blue limestone, and enter on one of the largest formations of this sort on the North American continent. The writer has traced this formation from near Salt Lake City to a point in Colorado, distant near 300 miles, the same general characteristics being prominent the whole distance.

In this formation where the mountains reach an altitude of 10,000 feet and the thickness of the strata is many hundreds, is situated

The Carbonate Mining District.

The most prominent of the mines here now and around which there is much interest is the Copper King, which is a large mine, bearing copper ore of unusual richness and fineness. This mine exhibits a peculiar feature, in that there is no low grade ores produced, and that all ore taken out is of an even richness and does not vary enough to allow of being assorted. It runs from 60 to 70% copper. This mine was discovered by Sam Montgomery three years ago, but the vein was not really found until a few weeks back. Ben Heater, Bob Turner, James Harz and others have been to work in an obscure way, but with a quiet determination which should be rewarded. In this case the reward has come, and the boys feel that they have ample pay for the hardships and hard knocks they have had. Some evidences of the amount of labor expended on it can be seen in the many prospect holes near by, every one of which is fifty feet in depth and shows nothing but mineral. The lead proper just unearthed shows now about four feet of the richest kind of ore; how much wider, is not yet known, but at present only one wall has been found. The lead works easy, the copper ore coming out in big chunks, which is intermixed with beautiful yellow sand carbonates. The mine is situated near the top of one of the high mountains, and is between a contact of beautiful white quartzite and blue lime. A short distance below is a fine strata of hematite of iron, and still lower in the contact of the old red sandstone, showing very clearly that this bed at least lies near the bottom of this gigantic formation of lime. Immediately above the mine towers a high cliff of limestone, quartzite, flints and various other strata incidental to this period. From the dip of the lead to the southwest and the huge masses above, we naturally infer that the other mines which lay southwest of here will be deep.

There is now about a carload of rich ore on the dump awaiting spring for shipment. Besides the copper ore, the ore runs about 20 ounces silver, and I believe a trace of gold, with a strong marked improvement in the silver assays as depth is attained.

The Amazon exhibits some strong croppings of copper and galena ores, and it is down about 15 ft.

The majority of the claims taken up here some three years ago, during an influx of Colorado prospectors, are now open to relocation, and I have no doubt but that if some of them were properly prospected they would prove of value.

The Union Consolidated Mining Co. are interested in some claims here, but what the company design doing I do not know.

This camp presents many desirable features of great value, the most noticeable of which is

the supply of good timber, which is far better than the average of our Utah timber. Parsons & Oakley have a fine saw-mill located in the center of the camp, and have cut some good lumber.

Botanizing in the Land of the Apaches.

In August, 1881, after the rains had partially subsided on the desert of Arizona, Prof. Lemmon and his wife started on their third summer's exploration in Arizona. From observations from the train of the Chiricahua mountains the season before, they supposed that that would be a good range of mountains to visit.

After several detentions on the desert, they arrived at Bowie station in the night. Bowie station is a military post on the railroad, and is composed of but a few houses. Here they expected to find a friend, and, when the train left, began calling for him. For some time there was no response, but finally a light appeared in a tent north of the station and a man emerged and asked, "What's wanting?" Out came another man, girl about with a belt containing pistols and cartridges, with knives in his boots, and then another, until finally there were five of them. Prof. Lemmon told them that they desired shelter for the night, and Capt. Tevis, a noted character of the region, vacated his own quarters and gave them up to the botanists. He locked them in and left them a brace of pistols, saying, "You may have to use them before morning."

An adjoining cabin was filled with cowboys. The storm which had been brewing now broke with terrible violence, and the water came down in torrents. During the lull after a clap of thunder, a voice was heard to say, "Let them mules alone. Git!" And in the morning they were told that the cowboys had endeavored to carry off the mules, but were discovered and stopped. In the morning the sun came out bright and beautiful, and they went out botanizing, up to their knees in beautiful flora. About noon the next day an ambulance came, as per agreement, from Fort Bowie, with Surgeon Ord and wife, whose guests Prof. and Mrs. Lemmon were to be.

They crossed a plain and then up through a wonderful pass, called the Apache Pass, which contained the only spring for many miles. Here the Apaches would lie in wait for the thirsty travelers and shoot them down. In this pass is a graveyard filled with little headstones, which read, "Killed by the Apaches, name unknown." The work of the Apaches may be understood from the statement that they reduced the population of Arizona from 60,000 to 10,000. This pass was now filled with beautiful flora and was a most enchanting place. They first began picking flowers and putting them in a press, then filled every available spot in the ambulance until, five miles before they reached their destination, there was room for no more.

They remained at the fort some three or four weeks, though they had expected to go south sooner, but were detained at the fort on account of the breaking out of the White Mountain Apaches. Their real objective point was to make a short stay at Fort Bowie and then to go on to the deserted Camp Rucker, in the southern part and highest point of the Chiricahua mountains. At length, having been assured that the Chiricahua Apaches were friendly and that they would be perfectly safe, they started out in an ambulance with a guard to protect them from the cowboys, and provisions for three weeks. They started on the 21st of September, the day of Garfield's death, which they did not hear of for 10 days. They met with numerous adventures, and arrived at 10 o'clock at night at a ranch house, where they stayed all night. They took an early start the next day for Rucker valley. The scenery became wonderful; they appeared to be entering an amphitheater of rocks. The rocks had assumed all forms; monks going to confession with the cowls over their heads, and in supplicating attitudes, and through all the most beautiful flora.

Prof. Lemmon bore letters of introduction to a curious old hermit, the only occupant of the whole valley, calling himself Dr. Monroe. That was their objective point. As they approached his cabin the noise of their feet stirred his lens to cackling; then the upper part of his door opened, and the old hermit appeared—a little old man with a hooked nose like an eagle's, a dilapidated straw hat over his right ear, long, fine hair, streaked with gray, and piercing black eyes. His clothing was half military and half frontiersman. He read the letter, and then opened the lower part of the door and invited his guests in. The guard of soldiers returned to Fort Bowie, but were to come for the excursionists at the end of ten days.

The hermit entertained his guests with stories of his life and his instruments of defense, which consisted of a certain tunnel, so ingeniously constructed that it is worthy of description.

At the back of the cabin some sacks were carelessly hung, which, when drawn aside, disclosed what appeared to be a cellar, but which really was the opening of a tunnel 120 ft. long, with a double elbow in the middle and a cabin at each end. The tunnel was just high enough for himself, and he was a short man, only about five and a half feet high. The bottom and roof were rough with cobble stones. The middle was enlarged to allow for storing and defense. It was very

dark, and unless one was acquainted with it, it was of no use to try and follow the hermit. For defense, in case he was overpowered, he had an arrangement of fuse, carefully covered over with rock and cobbles, which when fired would blow up everything.

This Dr. Monroe was a very intelligent man, and had evidently moved in high circles. He had had some 23 different occupations in life, from playing the clarinet in a circus to teaching school in Virginia and practicing medicine. Hanging over the fireplace was not less than 12 hats, in different stages of dilapidation, and he was never seen without one of these on. He never put it square on his head, but always on one side. He kept cats and chickens, and when asked why he did not have a dog, he said that several years ago he had a partner in a mining scheme, and they had a dog which was considered very faithful. One day the partner returned to the cabin to get dinner, and when Dr. Monroe reached it an hour later he found his friend dead. The dog had not given the alarm of the approach of the Indians, but had skulked off and hid. After that he never had any faith in dogs.

Time passed. One morning Prof. Lemmon was out botanizing, and Mrs. Lemmon was alone at the cabin, when a rider came up and said he had ridden all night to warn them that the Chiricahua Apaches had broken out and were starting for their old stronghold, the very valley where the Professor and his wife were peacefully botanizing. He brought a letter from Dr. Ord and wife stating that they were powerless to help them, and advising them to secrete themselves in the mountains and they would come to their relief as soon as possible. It was a time of great anxiety, and they were hammed in for 11 days before an officer came saying that Capt. Rafferty was but four miles away and would escort them back to Fort Bowie.

They reached Fort Bowie in safety with a great many plants. A new genus of fern was named after Mrs. Lemmon. They discovered many other new things, and altogether it was a very successful trip.

Deposits and Lodes in the Mining Laws.

Ever since the discovery of the "blanket lodes," or deposits at Leadville, Col., the fact has been recognized that the United States Mining Statutes are at fault in not properly providing for the location of this class of mineral ground. The law supposes a man will find the apex of the lode sticking out of the ground somewhere, but in this (as in many other things) the law is mistaken. The law does not give any definite ownership of mining ground until the mineral-bearing lode or deposit itself is found. When, therefore, miners search for "blind lodes," or horizontally lying and deep deposits, they have no rights at all till they strike the deposit or lode. The reading of the law is such, as miners know, as to provide more for lodes than deposits. In order to overcome these objections the miners of Colorado have memorialized Congress in the following terms:

WHEREAS, The geological formation and other evidences indicate the existence of valuable deposits of carbonate and other ores in many localities within this State; and

WHEREAS, Owing to the horizontal position of such deposits, they are seldom or never discovered except by boring or sinking deep and expensive shafts; and

WHEREAS, The laws of the United States on the subject of mining are not construed to give any right of possession to the surface of any definite area of mineral lands of the public domain until after the discovery of mineral in rock in place on such lands; and

WHEREAS, The right of possession and occupation of some definite area of such lands is necessary to encourage the expenditure of labor and money to sink for the discovery of mineral; your memorialists respectfully request the enactment of a law granting the right of location, possession and occupation of claims on such supposed mineral lands, such claims to be 10x10 or 5x20 chains, and contain 10 acres each, and conform to the public land surveys, when located on public lands, and that the right of possession of such locations continue so long as the locators expend \$100 in labor or improvements each year on such locations, and for the purpose of enabling such locations to determine the true character of such supposed mineral lands with the least possible delay or expense; that locators be allowed to consolidate any adjoining locations not exceeding 10 in number, and expend all labor and improvements in one or more places on such consolidated locations, and that the right of occupation and possession to each claim so located and consolidated continue so long as the amount of money expended or improvements made on such consolidated claim shall equal \$100 each year for each claim so located and consolidated, and that locators of such claims be entitled to all mineral discovered in claims between vertical planes drawn downward through the surface boundaries of such claims to any depth, and that such claims, when located on surveyed lands, may be described as subdivisions of the public lands, and that patents for such locations may be obtained under such regulations as Congress may determine.

Right of Way of Mining Ditches.

An artificial water course through the land of others is strictly an easement, and the right to construct it is the subject of contract or agreement. At common law the right may be acquired by an uninterrupted adverse user of 20 years. It is not understood that the few cases in which the rule of prescription has been applied in this State to water from a natural stream has any application, or at common law, to artificial streams. In addition to the special legislation applicable to certain agricultural counties, for the purpose of irrigation, and expressly excepting the Acts from affecting the mining interests of this State, passed in 1854, and amended in 1862, and corresponding with the Mexican *Ordenanzas de Tierras y Aguas*, there has been some legislation authorizing the incorporation of canal companies for irrigation, mining or manufacturing purposes. Acts by the State and by the United States leave nothing unprovided for, so far as respects the public lands. When, however, private lands are to be crossed on the route of a canal or ditch, proceedings must be taken to obtain the right of way.

A case of interest to miners in this connection has been decided by the Supreme Court of the State. The case was that of Henry Lorentz et al. vs. Henry Jacob, the decision being rendered by Judge Morrison, and concurred in by Judges Myrick, McKinstry, Ross and Thornton. Plaintiffs commenced proceedings in this case under Sec. 1,238 of the Code of Civil Procedure to condemn certain lands belonging to the defendant for the purpose of a ditch then under process of construction by them. It is alleged in the complaint that the plaintiffs are now constructing and completing a ditch for the purpose of carrying water from a certain point on Connor creek to plaintiffs' reservoir on Red hill, in Trinity county, and that the uses for which the water is intended and designed are mining and irrigation. The Court below entered a judgment in conformity to the prayer of the complaint, and defendant appealed.

The decision is as follows:

There are two points made by the defendant's counsel which we will briefly consider: First, the findings are insufficient to support the judgment, and second, the evidence shows that the use for which the property is sought to be taken is a private use.

The following are some of the findings:

"3. That one of the uses for which the proposed ditch is intended is the sale and rental of water for mining and agricultural purposes.

"9. That the use to which plaintiffs intend to devote the proposed ditch is for the sale, rental and distribution of water to the mining claims and agricultural land in said Red Hill mining district, including mining and agricultural land belonging to said plaintiffs, and is not a purely private use."

At the request of counsel for defendant the following additional finding was filed by the Court:

"5. With the exception of plaintiffs' own mine, the owners of the different mining claims and agricultural lands mentioned could be served with water by means of ditches already in existence, and have been so served with water in former years. The ditches so used have ample capacity to carry the waters of Connor's creek, except in times of exceptionally high water. Some of these ditches have fallen into disuse, or have been worked away, and with the exception of the Connor ditch, the Jacob's ditch, the Mackey ditch and the Butcher ditch, none of these ditches have rights of water of any value, either for mining or irrigating purposes. To serve the various claims and agricultural lands with water through these old ditches by letting the water run down Connor's creek would involve a great waste of water, unless purchasers would take it at all times, night and day."

The conclusion of the Court below was: "In conclusion, after a careful examination of the evidence offered, the following appears to be the true state of the case: Plaintiffs are the owners of the most valuable interest of any in the waters of Connor's creek, which stream is the only one available for working the mines in the Red Hill mining district. This water they have used for many years past in working their own mines, occasionally renting some to others for mining or irrigating. Plaintiffs cannot work their mine to advantage by means of ditches now in existence, and rather than have their water become worthless, they propose to make a public use of it, in which use, as a part of the general public, they will be entitled to a share. The question is not free from difficulties, but in my judgment the statute should be liberally construed in a mining country; and if it appear that the intended use is a public one to a reasonable extent, the right of way should be granted."

We think that both points are well taken.

The findings are insufficient to show that the use for which the water was intended was a public use, and it clearly appears from the evidence that the main and substantial object of plaintiffs is to use the water in working their own mining claims. Private property cannot be taken for such a purpose. (The Wilmington Canal and Reservoir Co. vs. Dominguez, 50 Cal., 505; Cummings vs. Peters, 56 Cal., 593; Bankhead vs. Brown, 30 Iowa, 540.)

Judgment and order reversed, and the Court below is instructed to enter judgment in favor of defendant.

The Horn Silver mining company, of Utah, will pay a quarterly dividend of \$300,000 at New York on the 15th of February. This company paid four dividends of that amount last year. The pending dividend makes a total of \$2,000,000 given to stockholders.

Dust Explosions in Mines.

The subject of dust explosions in collieries and flour mills appears to have received a considerable amount of attention in the U. S., and Prof. Abel, F. R. S., lately delivered a lecture at the Royal Institution on the dangerous properties of dust. Few persons are aware how frequent such explosions are; they have been briefly alluded to, and it is stated that those who are conversant with this subject are of opinion that not more than 20 per cent. of the explosions that occur are made public because, unless the damage is serious, mill owners and others are unwilling to direct attention to the risks of their business. A very interesting quotation is given from a special report on the subject prepared for the Board of Trade. All the dust floating about a flour mill, common flour, "stive" dust from millstones and purifiers, the dust from the beams of the mill, from wheat cleaning machines, and especially, it is said, the "stive" dust from millstones grinding rice, all such dust is, under certain conditions, found to be very explosive. The quotation alluded to gives a very clear and intelligible explanation of the phenomenon which has lately been believed to be responsible for many mining accidents. It is merely a manner of rapid combustion; the finely divided dust particles being diffused in the air, are each brought into intimate contact with the oxygen, which is necessary for their combustion, and consequently when ignition occurs it is very rapid; the particles near the flame are ignited, and in their turn ignite the neighboring particles, which again ignite the adjacent ones, until the whole chamber is a body of flames. Touching this matter, an invention for the prevention of dust explosions in collieries and for other similar purposes, and for allaying such dust, has just been brought under our notice. We understand that it has been favorably reported upon by some of the leading colliery and other engineers, that it can with advantage be adopted for the prevention of explosions from coal dust. The invention is that of Mr. Stanley, and it is being introduced by Mr. William Thompson, of No. 12 York Buildings, Adelphi. For railways and mines, Mr. Stanley proposes fixing on a carriage a shallow tank, and above it, on supports sufficiently low to freely allow of its passing through the tunnel, another similar tank for water. Between the two tanks, at a distance of a few inches apart, perforated metallic tubes or wire gauze may be placed, which will conduct the water from the upper to the lower tank, which in thus gravitating through the perforated pipes, or down the gauze, will prevent the impure air a thin film of running water. The perforated tubes or gauze may be covered with flannel or other fabric, which will have the effect of retaining the water and prevent its flying off by the rapid motion of the carriage through the air. To keep a constant supply of water in the upper tank, Mr. Stanley uses a pump of sufficient capacity to keep the upper tank supplied with water from the lower one. For this purpose he utilizes the motion of the carriage, and works the pump from a drum fixed to the axle. Other motive power may be used such as compressed air, gas or steam. For collecting as much air as possible in passing, wings or louvers are, where practicable, to be hung to the carriage.

Considering that colliery owners run great risk of explosions from atmospheric and other causes, it is to their interest, independently of their responsibility as the guardians of the lives of their workmen, to adopt most stringent regulations and efficient precautionary measures for abolishing this source of danger, and to devote their energies to the application of improved arrangements for reducing the danger arising from the presence of dust, which not unfrequently results in the loss of valuable lives, besides entailing great pecuniary losses. In addition to all this they are responsible, under the Employers' Liability Act, for compensation both to widows and children of those who have been killed. We are informed that a joint report upon this invention has been made by Mr. Galloway, of Cardiff, and Mr. Howard, of Chesterfield, to the effect that it could be advantageously introduced at certain points in the workings in order to create damp localities, which would arrest the flame of coal-dust explosions, and that in mines, or parts of mines in which black damp, or carbonic acid gas, is given off by the strata or produced in any other manner, this apparatus, either locomotive or stationary, could be used with advantage for the purpose of absorbing that gas by means of caustic lime placed in the upper tank. The water would absorb a certain proportion of the lime, and in flowing down the tubes or rods it would take up the gas; the lime would thereby be precipitated, and would, for the most part, collect in the lower tank, from which it could be removed as required. The apparatus would be more especially applicable in localities where sprinkling water on the floor causes the latter to "heave" in such a manner as to disarrange the underground tramways, and gradually to fill up the roadways and railways, thereby occasioning much trouble and expense for repairs. On the whole, the invention appears to be one of promise, and we shall hope shortly to hear of its practical adoption.

GLASS VARNISH may be made of pulverized gum dragant, dissolved in the white of eggs well beaten. Apply with a brush carefully.

USEFUL INFORMATION.

Vanderbilt on Fast Locomotives.

A provincial paper prints a story that Mr. William H. Vanderbilt, the President of the New York Central and Hudson River railroad, has ordered his master mechanics to devise large and fast locomotives, capable of hauling 15 heavy drawing-room cars at the rate of 60 miles an hour. In it the statement is made that he offers a prize of \$50,000 for the best plan for an engine that will accomplish this work.

When asked by a *Times* reporter if the statement were correct, Mr. Vanderbilt replied: "There is no truth in that story. Why," said he, "engines leave the Grand Central depot every day that haul 13 cars and run at the rate of 60 miles an hour. We are not going to pound the road to pieces by putting on larger engines. If one engine will not haul a train we will put on two, and if necessary, add more trains; that is all. If a train is run by schedule 40 miles an hour, the rate is 60. Suppose a stop of 20 minutes is made for refreshments, and the train is late. The conductor will wait the full time at the station, and let the engineer make it up. I do believe," said Mr. Vanderbilt, smiling at his supposition, "that if an engine could run 140 miles an hour, and could cover a certain distance at the rate of 30 miles, the conductor would hold the train in order to run at the full 140. If an admonishment is administered, the operation is repeated as soon as your back is turned. No, we have engines that are fast enough."

MOLECULAR STRUCTURE OF METALS.—It is generally held that although most of the known metals are crystalline, they cease to be so when in a rolled state. Whether this be strictly true or not has never been put to the test, but recent experiments by M. S. Kallischer prove that foils of the metals can be made crystalline under the influence of heat. One result of the change is an increase of their electric conductivity. Non-crystalline zinc foil becomes crystalline at a temperature of 150° Cent. Tin and cadmium foils become crystalline at temperatures ranging from 200° to 280° Cent. Iron and copper show traces of crystalline structure when left in contact with nitric or hydrochloric acid; but the best result is obtained when the plates are made the positive electrode for the electrolysis of potassium or copper sulphate or nitrate. Specimens of brass containing 36 to 66 per cent. of copper showed a crystalline structure when made the positive electrode of solutions of copper sulphate or nitrate. In these cases the electric current does not, in M. Kallischer's opinion, produce the crystalline state, but rather the solvent power of the electro-negative constituent of the electrolyte, for it is observed that metals which do not show any crystalline appearance when corroded by free acids or solutions of salts, do not show it under the influence of the electro-current. Lead foil is crystalline; silver foil becomes so when heated red hot; gold foil exhibits a crystalline structure when heated and then acted upon with warm aqua regia. Platinum, as was observed by Phipson, becomes crystalline when warmed with aqua regia. Bars of copper, brass, steel, bronze, tin, zinc and cadmium have been carefully observed by Kallischer, and shown to have a crystalline structure.

PAYMENT FROM FIRST EARNINGS OF A MACHINE.—An engineer was employed to operate the engines of a company, and it was agreed that he was to be paid out of the first earnings of the machines. He had a settlement with his employers and they gave him a due bill for the amount due, and on this he brought suit, to which the defense was set up that payment only was demandable out of the earnings aforesaid, and that there as yet nothing had been earned. Judgment was entered for the plaintiff, and the defendants appealed the case (Harkinson vs. the Dry Placer Amalgamating Company) to the Supreme Court of Colorado, by whom the judgment was affirmed. Judge Stone, in the opinion, said: "The question is one of practical interest not infrequently arising in business ventures, and we have been at some pains in its investigation. The agreement did not expressly limit the payment wholly to the contingency of the machines earning enough to pay for the services rendered; and in the absence of an express limitation, it is not to be implied that the engineer agreed to look to the earnings alone for his wages. This condition can only be regarded as indicating an expected time of payment, but not as the sole condition of payment; and as a legal consequence of such an agreement, the wages would be absolutely due after a reasonable time for fairly testing the use of the machines. What is a reasonable time in all such cases is a question for the Court."

The thread industry of the United States, while it does not rank alongside the iron and steel industries in importance, makes quite a respectable showing, in figures at least. American manufacturers now turn out daily 12,000 dozen spools, containing 200 yards each; or, in other words, enough thread in six days to girdle the globe four and one-sixth times. The annual consumption of spools by our thread makers alone represents from 3,000 to 4,000 cords of wood. Foreign thread manufacturers who export largely to this country also use immense numbers of American spools, winding their thread upon them after the thread has paid duty at some of our ports. The consumption of the best grades of thread in our country is estimated at 21,000,000 spools per annum.

NEW METHOD OF SILVERING MIRRORS.—If glycerol is added to an ammoniacal solution of silver nitrate, it becomes brown after a time, and gradually deposits a black substance; this action is greatly accelerated by heating the solution, a portion of the silver being deposited as a steel-gray mirror. If a few drops of potash solution are added to the mixture of glycerol and ammoniacal silver, a brilliant mirror is soon formed on the interior of the vessel. The phenomenon is even more striking if the ammoniacal silver solution be first mixed with potash, and glycerol then added; directly the glycerol comes in contact with the silver solution, reduction takes place with formation of a brilliant metallic mirror. If either is added to the mixture of glycerol, potash, and ammoniacal silver nitrate, as soon as it touches the aqueous liquid, a metallic ring is formed at the junction of the two liquids, and in a few seconds reduction is complete through the whole bulk of liquid. If alcohol is added to the glycerol-silver mixture, reduction is somewhat accelerated, and the metallic mirror is always brilliant. The results of these experiments show that the reduction action of glycerol on silver salts may be applied technically with advantage to silvering mirrors, both from the facility with which the process may be conducted, and from its economy. The author, G. Palermo, promises details in a future communication to the *Gazetta*, from which the above notice is taken.

GLYCERINE FOR PRESERVING SKINS.—A mixture of glycerine and carbolic acid is highly spoken of for the purpose of preserving the skins of animals. Salting keeps the skins damp and prevents their putrefaction, but is objectionable, since it renders the leather less useful for various uses after tanning. Glycerine alone is not entirely satisfactory, but a mixture of glycerine and carbolic acid removes all disadvantages. The carbolic acid increases the preserving effect of the glycerine, while the glycerine keeps the skins perfectly soft and fresh, just as they were directly after slaughtering. Both substances are entirely without any injurious action on the substance of the skins, which are freed from them by simply washing, and are then in exactly the same condition for working as ordinary green skins. The method of using the preservative mixture is described as follows: The fresh skins are covered on the inner side with a mixture of 90 parts of crude dark glycerine and 10 parts of carbolic acid, by means of a plasterer's brush, and afterwards treated and packed as usual. Whether the advantages of this method have more than offset its increased cost above the common method, we are unable to state.

GOOD HEALTH.

Artificial Child Incubation.

The report of some remarkable experiments in so-called artificial child incubation comes from France. The *Glasgow Mail* says that the immense success which has attended the artificial incubation of chickens in France recently attracted the attention of Dr. Tavernier, a learned and ingenious physician. He was attached to a hospital for foundlings, and was annoyed at the large number of foundlings who died within the first six months of their life. The majority of those admitted to the hospital were weak and sickly, and he resolved to try what "artificial incubation" would accomplish if applied to infants. The doctor constructed a child incubator on precisely the model of the ordinary chicken incubator. It was a box covered with a glass slide, furnished with a soft woolen bed, and kept at the temperature of 86° Fah., by the aid of hot water.

He selected as the subject of his first experiment a miserably made infant, one that had come into the world at an injudiciously early period. This infant was placed in the incubator, provided with a nursing bottle, and kept in a dark room. To the surprise of the doctor, it ceased to cry on the second day after it was placed in the incubator, and although it had previously been a preternaturally sleepless child, it sank into a deep and quiet sleep. The child remained in the incubator for about eight weeks, during which time it never once cried, and never remained awake except when taking nourishment. It grew rapidly, and when, at the expiration of 60 days, it was removed from the incubator, it presented the appearance of a healthy infant of at least a year old.

Delighted with the success of the experiment, Dr. Tavernier next selected an ordinary six-months-old infant addicted to the usual pains and colic, and exhibiting the usual fretfulness of French infants. This child conducted itself while in the incubator precisely as its predecessor had done. It never cried; it spent its whole time in sleep, and it grew as if it had made up its mind to embrace the career of a professional giant. After a six weeks' stay in the incubator it was removed and weighed; during this brief period it had doubled its weight. It had become so strong and healthy that it resembled a child three years old, and it could actually walk when holding on to a convenient piece of furniture.

These two experiments satisfied Dr. Tavernier of the vast advantages of artificial child incubation. He immediately proceeded, with the permission of the authorities of the hospital, to construct an incubator of the capacity of 400 infants, and in this he placed every one of the 360 infants who were in the hospital on the 10th day of February last. With the exception of one

who died of congenital hydrocephalus, and another who was claimed by its repentant parents, the infants were kept constantly in the incubator for six months, when they were removed in consequence of having outgrown their narrow beds.

The results will seem almost incredible to persons who are unfamiliar with the reputation of Dr. Tavernier, and have not seen the report made to the French government on the subject by a select committee of 12. The average age of the infants last February was eight months and three days, the youngest being less than 12 hours old and the eldest not more than 11 months. Their average weight was 16 pounds, only one of the entire 360 having attained a weight of 32 pounds. At the end of six months of artificial incubation the average weight of each infant was 24 pounds, and there was not one who would not have been supposed by a casual observer to be at least three years old. In other words, six months of artificial incubation did as much in the way of developing Dr. Tavernier's foundlings as three years of ordinary life would have done. The infants were strong and healthy as well as big; they walked within a week of leaving the incubator, and most of them have since learned to talk. These results surpassed Dr. Tavernier's most enthusiastic expectations, and there can be no doubt that his system of artificial child incubation will be adopted not only in every child's hospital in France, but in every private family throughout the civilized world.

Too Fat.

The tendency to accumulate fat is constitutional; but it can either be checked or encouraged by the individual in whom this tendency exists. In spite of all protestations to the contrary, fat persons eat heartily; they may not consume as much food as some who are lean, but they require less, because there is more assimilation; that is, the nutrient portions of the food are more readily converted into fat, and there is less waste. All medicines that cause a reduction of fat do so at the expense of the general health. Bottled anti-fat remedies are simply bottled diseases, since it would be impossible to reduce the amount of adipose with one bottle or a hundred bottles of it, unless it was sufficiently powerful to derange the natural and healthful functions of the body and induce disease. It would be safer to accomplish the object by contracting fever and ague, or even small-pox.

There is a method, however, of reducing excessive fatness, which is not only safe but healthful, and which will insure greater comfort, and perhaps longer life to the individual. That is by the moderate use of the fat-producing foods, which are those containing starch or sugar. The individual should not discard them altogether, as was suggested by Banting, because in so doing obesity is generally changed for something worse, in form of fatal kidney diseases. An over-fleshy person should make a "bill of fare" for himself on a descending scale as to nitrogenous or fat-producing foods, and an ascending scale as to nitrogenous foods. He should diminish the quantity of wheat bread eaten at each meal down to one or two ounces; the same for fats and potatoes, and make up the deficiency with lean meats and bread made from graham flour, etc.

FATAL ACCIDENTS IN 1882.—The *Pittsburg Commercial Gazette* has evidently been keeping account of all the disasters occurring in 1882. The result is given out editorially in a recent issue of that journal, and only requires comparative statistics from former years to possess more interest, if not value. The totals are:

Tornadoes.....	590
Boiler explosions.....	198
Fires.....	128
Powder explosions.....	83
Falling buildings.....	72
Fireworks explosions.....	43
Deaths on lake.....	160
Floods.....	163
Mining explosions.....	152
Struck by lightning.....	26
Snow slides.....	81
Dynamite explosions.....	11
Death on the rails.....	320

Fatal calamities, by reason of railroad disasters, are thus seen to be by far the most numerous, yet feared by the public probably considerably less than death by flood or fire.

POISONING WITH WASHING SODA.—The *Pharmaceutical Journal* reports a case of poisoning of a child five years old from drinking a solution of washing soda, which occurred in Greenwich, England. The evidence of the mother was that on Wednesday she left the child at home by herself, and during her absence the child drank some water from a kettle on the hob in which witness had placed a handful of common washing soda to cleanse it before leaving home. On her return she gave the child some magnesia, and she vomited and did not appear much the worse, but the next day the symptoms were alarming, and she went to the Relieving Officer and obtained an order for medical attendance. On Dr. Hartt seeing the child he found her in a dying state, and gave no hopes of her recovery, and she died on Thursday afternoon. The child was in the habit of drinking from the kettle. Dr. Hartt, the parish surgeon, said the appearances of the child were consistent with alkaline poisoning, and the child must have suffered great pain. Three ounces of common soda dissolved in water had been known to kill an adult, and the deceased was presumed to have taken about an ounce. The jury returned a verdict that the deceased died from drinking common washing soda and water from a kettle by misadventure.

Passing Events.

There is little new to note from the mining regions this week, aside from what our Mining Summary relates. The cold weather retards mining operations, as a general thing, a good deal of out-door work being stopped. The freezing up of ditches, etc., has put the miners to great inconvenience.

Though the Legislature has been some weeks in session, very little has been done, so far, in making laws. One "debris bill" has been killed. Another one has been introduced this week, declaring hydraulic mining a "public nuisance," which is an odd title to give to an industry yielding \$14,000,000 of gold a year to the world.

So far, indications are not very favorable for a good water season this spring. The dry winter somewhat discourages the hopes of the miners.

THREE miners, R. S. Ehler, Joseph Griffin and James McKee, were killed by a cave in the Esmeralda mine, at Deadwood, Dakota. Thirty men were at work in the mine, but were warned by cracking timbers and escaped. The above-named went back after their coats, and were caught in the tunnel.

GILMER & SALISBURY intend putting on four-horse coaches between Ward and Eureka, Nevada. This is owing to the increased bullion output from the Martin White mine, at the former place.

Protection of Miners.

It may not be generally known that there is a law in force for the protection of miners, providing for more than one mode of egress from mines lower than a certain depth. This Act was passed March 13th, 1872. An act to amend this, introduced by Mr. Reddy at this session of the Legislature, has been approved by the committee, and passed the Senate. It is numbered Senate Bill No. 86, and is as follows:

Sec. 1. It shall not be lawful for any corporation, association, owner or owners of any mining claim, within the State of California, to sink down into such mine or mining claim any perpendicular shaft or incline beyond a depth from the surface of 300 ft., without providing a second mode of egress from such mine, by shaft or tunnel, to connect with the main shaft at a depth of not less than 100 ft. from the surface.

Sec. 2. It shall be the duty of each corporation, association, owner or owners of any mine or mines in this State, when it becomes necessary to work such mines beyond the depth of 300 ft., to proceed to sink another shaft or construct a tunnel so as to connect with the main working shaft of such mine as a mode of escape from accident in or about such mine or works.

Sec. 3. When any corporation, association, owner or owners of any mine in this State shall provide for the proper egress as herein contemplated, and where any accident shall occur, or any miner working therein shall be hurt or injured, and from such injury might have escaped if the second mode of egress had existed, such corporation, association, owner or owners of the mine where the injuries shall have occurred shall be liable to the person injured in all damages that may accrue by reason thereof, and an action at law in a court of competent jurisdiction may be maintained against the owner or owners of such mine, which owners shall be jointly and severally liable for such damages. And when death shall ensue from injuries received from any negligence on the part of the owners thereof, by reason of their failure to comply with any of the provisions of this act, the heirs or personal representatives of the deceased, or in case the deceased was a minor at the time of his death, by the father of the deceased, or in case of his death or desertion by him of his family, the mother or guardian may commence an action for the recovery of such damages as are provided by section 377 of the code of Civil Procedure.

Sec. 4. It shall be unlawful for any corporation, association, owner or owners of any mining claim, while engaged in sinking any shaft or incline, or working in or through such shaft or incline where there is no second way of egress or escape from such shaft or incline, and where steam hoisting works are used as the means of hoisting men and material out of such shaft or incline, to leave the said hoisting works in charge of but one person while any person may be engaged in working said shaft or incline, or in any opening therefrom beneath the surface.

Sec. 5. This act shall take effect and be in force from and after its passage.

Most people will probably be impressed with the fact that it would be difficult to enforce such a law as this without working a hardship on a certain class of miners. If, as soon as a man has a 300-foot shaft on his mine, he must immediately stop work sinking, until he has put down another 300-foot shaft, it is highly probable he will stop at 299 ft., unless he finds something to pay. Tunnels are only possible in few localities. Mining is a hazardous occupation, and every possible safeguard should be thrown around the men who follow it. Still, some chances must be taken, and it is hardly politic to enforce such measures as will retard development. In many instances the enforcement of a law requiring a supplemental safety shaft would cause the closing down of the mine altogether.

QUICKSILVER BY THE FLASK.—A new department in the sale of quicksilver is announced by Mr. J. B. Randol, who will in the future sell the celebrated A brand (from the New Almaden mine) by the flask. Heretofore the product has always been quoted by the pound. The new way is in conformity with the custom in London, the great market of the world. The flasks all contain 763 pounds, and the quotation is "\$26.50 per flask, with price subject to change without notice." Car-load lots will be shipped from San Jose, for Nevada, Arizona and New York, or delivered at the P. M. S. S. Co's wharf and depot of S. P. R. R., S. F., without charge. The railroad rates from San Jose are the same as from Santa Clara. There is no reason why quicksilver should not be quoted by the package in this way as is the case with most other products.

A PROSPECTOR gives this way of telling mines belonging to incorporated companies: "When no one will tell you anything about a property, and the only knowledge to be obtained is by what one can pick up by one's own observation, the mine may be set down as belonging to a company." We concur. And it may be added that most mines evidently belong to incorporated companies, or else the above theory is incorrect.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday evening, Prof. Davidson in the chair. Count J. Lambertenghi, Italian Consul, Dr. Paolo de Vecchi, Wm. R. Eckert and S. B. Leavitt were elected resident members, and Henry B. Osgood, Dr. F. V. Hopkins, Miss M. H. Jones and Mrs. Donald McLennan were proposed for resident membership.

The Council announced the appointment of the following curators in the different departments for the year: On birds and mammals, E. F. Lorquin; fishes, Charles G. Yale; radiates, reptiles and crustacea, J. J. Rivers, Curator of the State University Museum; ethnology and osteology, A. B. Stout, M. D.; botany, Justin P. Moore and M. K. Curran; entomology, H. Herman Behr, M. D.; conchology, Josiah Keep; mineralogy, C. D. Gibbs and J. T. Evans; geology and paleontology, Edward Booth.

The following members of the Academy have recently formed a microscopical section: J. P. Moore, Henry Ferrar, W. F. Meyers, Dr. F. V. Hopkins, M. K. Curran, M. D., Chas. G. Yale and George Davidson.

A letter from the Board of Trustees announced that that body had elected Geo. E. Gray, President; Thos. P. Madden, Vice-President, and C. W. Brooks, Secretary.

Mr. J. W. Forsyth read a paper on "Cinchona and the Method of its Cultivation in Ceylon and East Indies."

J. G. Lemmon read a continuation of his paper on "The Potato," this portion being mainly a compilation of facts connected with the history of the potato as an edible.

President Davidson announced that the observer at the tide gauge at Fort Point reported that the temperature of the sea water along the coast had ranged lower the past month than for 25 years past.

Banner Quartz Mine.

This mine, located four miles north of Oroville, is the principal quartz mine in Butte county. The ledge, or rather lode, courses north and south to the east, the hanging wall being porphyry and the foot wall slate. The thickness of the quartz vein averages from 20 to 24 inches. The mine is opened by a shaft down 300 ft., and about 2,000 ft. of drifts at the 100 and 200 levels. The hoist is steam-power, and of sufficient capacity to sink the shaft 1,000 ft. There is also a new and finely equipped 10-stamp mill on the property. The ore is free-milling, and contains but a very small percentage of low-grade sulphurets.

Like most of the Butte county quartz mines, the Banner is not uniform or regular in the gold yield of its ore. In the aggregate, about 10,000 tons of ore have been milled, and have yielded \$600,000, an average of \$60 per ton. This is a showing that very few of our California quartz mines can equal. Taking into consideration the little depth that has been explored, it seems probable that the future yield of the mine will be far in excess of its past yield. Work has recently been recommenced, and indications of the existence of a new ore chimney on the 200 level found.

The successful development of this mine will give quite an impetus to quartz mining in the numerous ledges in the vicinity. Many of these latter have proved very rich in the surface workings, but no depth has yet been attained to determine their permanence.

TWO THOUSAND CARS OF BULLION.—The Mingo smelter began operations January 1, 1877, since which it has run most of the time, and yet at one time it laid idle for nearly four months. Its product of lead bullion has been steady and reached an enormous aggregate. Last Saturday it completed its shipment of 2,000 cars, which were sent East. The average was a little over 13 tons to the car, making an aggregate of over 26,000 tons. Most of the ore is brought to the smelter by rail, and all the fuel and fluxes are delivered to the works by the car load, and it is estimated that it required nearly 10,000 car loads of ore, iron, limestone, charcoal, coke, coal, etc., to produce this vast pile of bullion. With such figures as above, one can readily see the important part railroads perform in a successful smelting enterprise, like that of the Mingo Furnace Company.—*Salt Lake Tribune.*

THE Grass Valley Union says that the impression prevails that the coming season is going to be more active in quartz mining than for several years past, as some new operations are getting under way, and others that have been taking a rest will be started up, and then the introduction of water power is looked for to give an additional stimulus to the business.

THE last big pearl caught in the Gulf of California sold for \$14,000.

Manufacture of Ice.

(CONTINUED FROM PAGE 89.)

It has always been a great desideratum to obtain compression without heating the working parts of the machine, and this Mr. Lount has accomplished. All stage compression is avoided, and with a single pressure, without the use of water, the air is highly compressed. It is really high compression without the annoyance of water jackets or water injection in the cylinder. The air can be compressed to any pressure the metal will bear at one time, without the wearing parts being subjected to any injurious heat. It will be well for miners and all using air compressing pumps to examine this one.

In working the ice itself, Mr. Lount constructs a congelator consisting of rows or flat coils of pipe, which are placed in an upright position in the water to be frozen, and supported in such a manner that the sides—top and bottom edges—and one end of the blocks of ice which are formed upon the congelator are not in contact with any solid substance.

A peculiar feature, and a very valuable one also, is the combination with the congelator of an agitator placed in the water and below the congelator, where it can be operated efficiently, and also permit free access at all times to the congelator or blocks of ice above it. With this, the ice formed is solid and clear, and does not come out as "snow ice," as is apt to be the case in still water.

Mr. Lount has invented a process of detaching the ice from the congelator without having to first loosen the same by heat. The blocks of

Section of Lount's Compressing Cylinder.

ice, which weigh from one to three tons each when formed, are prepared by a system of tubes frozen into them, and the blocks are divided through these perforations into pieces convenient for handling. There are several coils of pipe in each congelator, all in the same tank, and the ends of the coils are so connected by means of three-way cocks, placed outside the tank, that either one or more of them can be thrown out of the circuit, while the refrigerant is still allowed to circulate throughout the other coils. When a coil is thrown out of the circuit the ice can be taken off from it at any time without interfering with the formation of the ice in the coils which are still in circuit. Water is drawn into the tank from time to time, as the ice is taken out, and the operations of making and selling ice from the same tank can be carried on simultaneously and continuously by this means. In fact, there is no store-house required, as ice is kept in the tank where made, and can be taken out as readily as from a store-house.

Mr. Lount has made several of these machines, which are now in operation. Several new machines are also contracted for. The compressors are all made on this coast, and seem to be giving satisfaction wherever used. That in operation at Guaymas is the property of Wm. B. Hooper & Co., of this city.

THE Bonanza King mine still continues to do credit to its name. For the week ending Jan. 24th the bullion shipments consisted of eight bars of silver weighing 15,000 ounces, making a total shipment for the month, to that date, of \$48,000. A 10-stamp mill is turning out the bullion.

INDIANS are reported to be depredating in New Mexico. The Gila valley is again alarmed, and settlers are fearful of the repetition of the occurrences of last April.

Construction and Care of Dams.

Probably never in the history of the State has so much public attention been called to the questions connected with dams as of late, since the debris question has been discussed. The miners and the engineers, however, have always been greatly interested in these structures, of which there are so many in the mountains of California, doing duty in holding back the water supply for use in the drier seasons of the year. A case of some interest connected with the construction and care of dams has just been decided in Sierra county, and the result will serve to put careless people on their guard, in view of prospective damages in case of accident. The action was brought by the South Branch Water Co. against the Sierra Butte Gold Mining Co., to recover damages for washing away a bridge by the breaking of defendants dam, located at the outlet of Sardine lake.

There were two questions of fact to be considered: first, as to the care taken in the construction of the dam; second, the care taken of the dam after its construction.

The dam was constructed of logs, and from the evidence of I. G. Jones, a civil engineer, it appears the rafters of the dam were 14 ft. apart, and that they should have been seven. That the mudsills should have been sunk deeper in the ground, and that the spiling in front of the dam should have been sunk to the depth of at least six feet at the outlet of the lake, in the ravine at the point where the dam broke; the mudsill was three feet above the bed of the ravine, and that the double plank of two inches in thickness, or spiling in front of that mudsill extended below the bottom of the ravine three feet. It was also in evidence by Mr. Jones, that there should have been additional waste gates, that the water of the dam could be drawn off so as to guard against casualties, and to enable persons to repair the dam, etc. The dam was completed about the middle of July, 1881. Its height at the back of the dam above the ravine was 26 ft. At the north end of the structure a waste-way was constructed of 100 ft. in width, which, from its unusual width, would appear to be intended to prevent the water from being raised above a certain height, and for the protection of the dam. On the 19th day of July, 1882, the dam broke at the deepest point in the ravine, and was carried out by the force of the water. The break was 50 feet at the bottom and 71 feet at the top. About a week or 10 days previous to the breaking, the waste gate was planked up and the water of the lake was raised at least 15 inches above its previous height, or that intended by the construction of the dam.

On the 17th day of July, 1882, more than the usual amount of water was running out from under the dam, and one of the rafters (the second one from the top) near the center of the dam was breaking at that point. The structure appeared sunken. On the next day, July 18th, the dam was heard to crack, and the gate through which the defendants drew water from the lake for mill purposes was raised two inches. The lake contained an area of 160 acres.

Judge A. J. Howe rendered the decision which is published in the *Mountain Messenger*. The Judge says: Considering these facts it appears to the court, that the ravine widened and became deeper, descending from the front to the back of the structure, so that it does not appear how little or much support the spiling received from the earth behind it. The increased flow of water two days before the breaking, under or through the spiling, was the ultimate cause of the disaster, and that the spiling was inadequate for the purpose it was intended. The raising of the water, by closing the waste gate, appears to have been unwarrantable, as the dam very soon after appeared to be in a very critical condition, so much so that decided means should have been taken to relieve it, by drawing off the water of the lake.

The raising of the gate, two inches on the 18th, could not have given immediate or adequate relief to the dam, and this appears to be all that was done on that day to prevent the disaster that followed on the morning of the next day.

There appears to have been a gross neglect of duty, on the part of defendants, in the construction of the dam, and its care, considering the risks and damages likely to accrue to others, precipitating such a large body of water into the stream below their reservoir.

Judgment was entered for the plaintiff for the amounts prayed for, with costs.

Temperature in Mines.

The increase of temperature which accompanies increase of depth is the main cause which it is necessary to consider as limiting the depth at which it may be practicable to work. In this country the temperature of the earth is constant at a depth of about 50 ft., and at that depth the temperature is about 50° Fahr. The rate of increase of the temperature of the strata in the coal districts of England is, in general, about 1° Fahr. for every 60 ft. of depth. In some instances the increase is very irregular, being probably affected by local conditions, such as percolation of warm or cold water and varying conductive power of the rocks penetrated. These cases, however, are exceptional, and throw no doubt upon the general conclusion that the rate of increase amounts, as a rule, to about 1° Fahr. to every 60 ft. It may be observed in passing that whenever artesian wells have been sunk in this or other countries the rate of increase is in close harmony with that observed in English coal mines; but, on the other hand, by observations made in Belgian coal mines, the rate of increase appears to be less than in English colliers, though it is quite possible that this

Improved Boiler Scraping Attachment.

The accompanying engraving represents a new boiler scraping and cleaning attachment, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by J. M. Lakenan, of Grass Valley, Nev. county. It consists of a globe joint and stuffing box, through which a three-fourth inch steel scraper rod passes, with the scraper or brush attached, circled to fit the boiler. The scraper can be worked on bottom or sides, as high up as the tubes. The object of this invention is to enable the engineer to broom back any accumulation of scale or sediment on the bottom of the boiler to the blow-off pipe, and blow the same out of the boiler. This can be done while in use, and without running down steam or in any way interfering with the working of the machinery, which costs money and time.

The inventor says that it is well known by engineers that a few pounds of scale or sediment on the bottom over the fire will, in a few days, cause a blister or crack in the boiler, and should the opening be large enough, will throw the boiler out of its seating, and be called an explosion from some unknown cause, there being

METHOD OF TIMBERING IN STOPE.

apparent difference may have arisen from the thermometer, having been applied in a manner which would not correctly indicate the temperature of the strata. In the metalliferous mines of Cornwall the deviations from the scale of 1° Fahr. for every 60 ft. are very great, but it is very probably that the disturbing causes of variable conduction and percolation of heated water exists to a much greater extent in the geological formations containing metalliferous veins than in the sedimentary rocks embracing the coal measures. The deepest colliery in England is at Rosebridge, near Wigan. The tempera-

ture of the rock, as observed in this shaft, are in general agreement with the ordinary rate of increase to a depth of 1,800 ft., after that the increase becomes considerably more rapid, but it would be rash to conclude from this single example that the increase would in all cases be accelerated when that depth was exceeded. At the lowest point of this shaft the temperature of the earth, as indicated by a thermometer placed in a bore-hole a yard, is 92° Fahr.

Some little time since we gave a table showing the increase of temperature with depth at the Forman shaft, on the Comstock. This was March 25th of last year, so any one interested may obtain the PRESS of that date with the table. At 100 feet the temperature was 50½°; at 2,300 it was 121°. Holes cut not less than three feet deep were drilled into the rock and a slow-acting thermometer of the pattern adopted by the "Underground Temperature Committee of the British Association," was used. The holes were closed with clay and the thermometers were left in for 12 hours, not less than three holes being tried for each point. This will serve as a hint how to proceed to those who may desire to experiment in this direction.

three gangs of water at the time. The engineer in charge cannot at all times shut down and blow off to clean boilers; nor is it convenient to have a spare boiler. In the pumping of mines water is raising while boilers are being cleaned. Mills of various kinds are compelled to run during the week, and boilers neglected. This boiler scraper, being always left in the boiler, can be used any day or hour that the engineer suspects an accumulation, and if it is only removed from its place before becoming baked, it can do no harm, but it can be blown as well. The blowing off does not effect a

LAKENAN'S BOILER SCRAPER AND CLEANER

cleaning except for a few inches surrounding the discharge caused by the current. Thus the necessity of brooming the material back to the blow off pipe, so that the current may catch and carry it out. The rod A. passes through the stuffing box into the boiler, going through the pipe C. and globular head or universal joint D. This globular head D. fits a corresponding socket in the end of the stuffing box, so that the rod and stuffing box may have a movement around the head without leaking. The pipe C. fits into the boiler, being screwed in.

ELECTRIC LIGHTING IN TRAINS.—The Pullman train to Brighton is now lit with 40 instead of 18 incandescent lamps, owing to the employment of the new Faure-Sellon-Volckmar accumulator supplied by the Electrical Power Storage Company. In the first instance 70 Faure accumulators (original pattern) were required for the 18 lamps, whereas now there are only 30 Faure-Sellon-Volckmar cells used for the 40 lights, their total weight being considerably less than half that of the cells originally employed.

Notes from Eureka, Nevada.

[From our Own Correspondent.]

In my letter of last week I told you about my trip to Silverado mountain. It is situated in Pinto mining district, adjoining Eureka district, and is on the line that divides the counties of Eureka and White Pine. It bids fair to become the liveliest little camp in eastern Nevada during the coming summer. A few days ago a certificate of incorporation of the Berryman Tunnel and Mining Co. was filed in the Clerk's office. This concern has been organized under the laws of Nevada, for the purpose of developing six claims located last fall, on the east side of Silverado mountain, a short distance north of the Maryland and Diagonal mines, both of which, as stated in my last letter, are good ore producers. Each of the six claims are 1,500 ft. long by 600 ft. wide, and are so situated as to take in 1,500 linear feet of the mineral zone. It is all virgin ground, of a coarse, broken nature, and with bald croppings from one end to the other. It is proposed to break a face for a tunnel, the point of commencement of which has not yet been decided. Mr. Berryman, the superintendent, who has had a great deal of experience in that section, will again thoroughly examine the ground and report to the company, when the work of development will be commenced.

I learn that the indications in the Hoosac mine are so good that ore may be struck any day. It has the appearance of a good property, and I believe that Mr. Probert's foresight in purchasing it for the Richmond Company will soon become apparent. It is quietly rumored that the Richmond Company are securing new mines in this district, and it need not surprise anybody to find other large companies doing the same thing, as good mines can be purchased cheaply if the investor knows just the right course to pursue.

The tunnel properties are all looking well at present. The Ruby Hill tunnel, which enters Prospect mountain from the west side is a splendid enterprise. It is in only about 120 ft. but ore was struck in it a few days ago. The Company own all of the surface ground under which the tunnel passes.

M. H. JOSEPH.

Eureka, Feb. 5, 1883.

Mine Timbering.—No. 2.

In last week's PRESS we gave the details of forming stope timbers, and herewith give an engraving showing the general arrangement of the timbers in stopes. The timbers are usually of 12-inch stuff, square hewn or sawed. In one mine cited by Mr. Hague, on the Comstock, the posts of the sets of timbers like those we described last week, and such as are here shown, are 7 ft. 2 inches high, including the tenons. These latter 8 inches square, or 8x10, are 9 inches long on the upper end of post, and 2 inches long on the lower end; and as the caps and sills have half-inch shoulders cut for the admission of the ends of the posts, there remain 2 ft. 3 inches in the clear between the sills and caps of each set. The sills and caps 3 ft. 9 inches in the clear, also, have short tenons on each end, and shoulders cut to receive the ends of the posts and horizontal cross pieces. In some cases the method of framing is varied to suit the varying condition of the ground, so that, if the pressure is chiefly a vertical one, the tenons of the posts are cut as described, bringing the ends of each post in direct contact with its neighboring post, above and below, without introducing between them the tenons of the horizontal timbers, which would offer less resistance to a pressure at right angles to the fiber of the wood; while if the pressure be lateral instead of vertical the tenons of the posts are made short, and those of the horizontal timbers long, so that the latter may press directly against each other without the intervention of the post-tenons.

THEY have been having frozen quicksilver at Butte, Montana. When last heard of the thermometer was 48° below zero, with a downward tendency. At the smelter, a mile from town, 60° below is reported.

Metallurgy and Ores.

"THE \$1,000 CHALLENGE"

Ore Feeder for Quartz Mills.

OVER 800 ARE NOW IN USE, GIVING ENTIRE SATISFACTION.

Awarded First Premium at the Tenth and Twelfth Industrial Fairs of the Mechanics' Institute.

Twenty Per Cent. More Ore Crushed with Fifteen Per Cent. Less Wear of Iron than by and Feeding.

The accompanying cut illustrates the recently introduced Grip, and also the Spring Attachment, which replaces the Weight heretofore used, and which are obvious improvements.

It is now fully demonstrated, after careful and long continued experimentation and practical use, that the plan upon which a perfect Ore Feeder must be constructed is that of a carrier, and not that of a shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plate or table, to the line of discharge, and there simply dropped. Jerky or spasmodic outpourings will not answer the purpose for wet or sticky ores.

The Challenge Ore Feeders are now in Use in the following Mills, besides many others:

Son'sby.....	20 Stamp.....	Tuolumne county, Cal.
Sheep-Ranch.....	20 ".....	Calaveras " "
Mahoney.....	40 ".....	Amador " "
Zelle.....	40 ".....	" " " "
Placerville.....	40 ".....	El Dorado " "
Gross.....	80 ".....	" " " "
Julian.....	20 ".....	Placer " "

Providence.....	20 ".....	Nevada " "
Omaha.....	10 ".....	" " " "
Green Mountain.....	60 ".....	Plumas " "
Plumas Eureka.....	60 ".....	" " " "
Pulver-standard.....	30 ".....	Bodie Dis. Mono, " "
Standard.....	20 ".....	" " " "
Noonday.....	30 ".....	" " " "
Bodie.....	10 ".....	" " " "
Christy.....	5 ".....	Utah Co. Utah, " "
Ontario.....	5 ".....	Parley's Park, " "
Contention.....	20 ".....	Tomahstone Dis. Arizona " "
Grand Central.....	20 ".....	" " " "
Harshaw.....	20 ".....	Patagonia, " "
Sunshine.....	20 ".....	Idaho Springs, Col. " "
Homestake.....	20 ".....	Black Hills, Dakota. " "
Father De Smet.....	30 ".....	" " " "
Haddu Treasure.....	40 ".....	" " " "

Superiority of the "Challenge" Ore Feeder Demonstrated!

At the "Christy" Mill, Utah County, Utah, the "Eclipse" Feeders, (conceived by E. Coleman) were introduced, but not carrying a regular supply of ore for the crushing capacity of the stamps, were replaced by the "Challenge," which are now running and the stamps crushing forty (40) per cent. more ore than was done by the "Eclipse."

The "Harshaw" or "Hemosa" Mill, of Patagonia District, Arizona, was also originally fitted with "Eclipse" Feeders, but after a few weeks trial they were pronounced inadequate to the work, discarded, and the "Challenge" adopted.

The "Silver King" Mill of Arizona, also removed the "Eclipse" Feeders to give place to the "Challenge."

The "Soia" Mill, of Brown's Valley, Yuba County, Cal., was fitted with "Victor" Feeders, manufactured by E. T. Steen, but proving insufficient, the "Challenge" Feeders were substituted.

Four of the "Victor" Feeders, manufactured by E. T. Steen, were also placed in the "Alexander" Mill, at Grantsville, Nevada, but after a fair trial were discarded, and Henry's Feeders fitted, and four others of the same pattern adopted when the second twenty stamps were erected.

These cases are simply cited from among many similar instances, in proof of the vast superiority of the "Challenge" Feeders over all others.

JOSHUA HENDY, Agent,

Machine Works 49 and 51 Fremont Street, San Francisco.

Manufacturer of Quartz Saw Mill and General Machinery. Also Agent for BAKER ROTARY PRESSURE BLOWERS, and WILBRAHAM ROTARY PISTON PUMPS. P. BLAISDELL & CO.'S Machinists' Tools. HOT POLISHED SHAFTING from the Akron Iron Company, of Akron, Ohio.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

CURIOUS MINING ACCIDENT.—On Friday night, while working a power drill in one of the drifts of the Idaho mine, one of the clamps holding the column became loose, and caused the drill to fall. As the compressed air was on with a full head the drill continued to drive its lighting blows at random, and to the great danger of William Rogers and James Richards, who were working it. In the caving of the machine, before the compressed air was shut off, Rogers was bruised about the breast, hips and legs, and Richards had one of his fingers mashed, but none of the injuries were of a serious nature.—*Grass Valley Union.*

Mining Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

ANNUAL STATISTICIAN of 1882.—"It is the most complete and accurate work of its kind in the world."—S. F. Call. Address L. P. McCarty, 502 Taylor st. Price, \$4.

TRUE Temperance

Is not signing a pledge or taking a solemn oath that cannot be kept, because of the non-removal of the cause—liquor. The way to make a man temperate is to kill the desire for those dreadful artificial stimulants that carry so many bright intellects to premature graves, and desolation, strife and unhappiness into so many families.

It is a fact! BROWN'S IRON BITTERS, a true non-alcoholic tonic, made in Baltimore, Md., by the Brown Chemical Company, who are old druggists and in every particular reliable, will, by removing the craving appetite of the drunkard, and by curing the nervousness, weakness, and general ill health resulting from intemperance, do more to promote temperance, in the strictest sense than any other means now known.

It is a well authenticated fact that many medicines, especially 'bitters,' are nothing but cheap whiskey vilely concocted for use in local option countries. Such is not the case with BROWN'S IRON BITTERS. It is a medicine, a cure for weakness and decay in the nervous, muscular, and digestive organs of the body, producing good, rich blood, health and strength. Try one bottle. Price \$1.00.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Licharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. R. Haggins for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. **HALLIDIE IMPROVED ORE TRAMWAYS.** We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretensions claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

THE CALIFORNIA POWDER WORKS,

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES Powder.
ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, San Francisco, Cal.

Pacific Rolling Mill Co.,

SAN FRANCISCO, CAL.

MANUFACTURERS OF

RAILROAD AND MERCHANT IRON,

ROLLED BEAMS, ANGLE, CHANNEL AND T IRON, BRIDGE AND MACHINE BOLTS, LAG SCREWS, NUTS, WASHERS, ETC., STEAMBOAT SHAFTS, CRANKS, PISTONS, CONNECTING RODS, ETC., ETC.

Car and Locomotive Axles and Frames, and Hammered Iron of Every Description.

HIGHEST PRICE PAID FOR SCRAP IRON

Orders Solicited and Promptly Executed.

Office, No. 202 Market St., UNION BLOCK.

L. C. MARSHUTZ.

T. G. CANTRELL

National Iron Works,

Northwest Cor. Main and Howard Sts., San Francisco, Cal.

MANUFACTURERS OF

IMPROVED PORTABLE HOISTING ENGINES

At Greatly Reduced Prices.

HOME INDUSTRY! ALL WORK TESTED AND GUARANTEED!

Stationary and Compound Engines, Flour, Sugar, Quartz and Saw Mills. A large variety of Lifting Machines.

CASTINGS AND FORGINGS OF EVERY DESCRIPTION.

Sole Manufacturers of Kendall's Patent Quartz Mills.

RICHARD C. REMMEY, Agent,

Philadelphia Chemical Stoneware Manufactory,

On O E Cumberland St., Philadelphia, Pa.

Manufacturers of all kinds of Chemical Stone Ware for Manufacturing Chemists. Also, Chemical Bricks for Glove Towers.

IRON MINE FOR SALE

An Iron Mine of three claims consolidated, situated two and a half miles from Kuerstord, on N. V. R. R. Contains very large body of high grade ore, samples of which may be seen at this office. For particulars address,

MRS. D. S. ROHLWING,
St. Helena, Napa Co., Cal.

Inventors' Institute

—OF—

CALIFORNIA,

321 California St., San Francisco.

Patented Inventions sold upon Commission. Agencies everywhere. Send stamp for Circular containing terms etc., or call at rooms of Institute for information.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot,

PARKE & LACY,

21 and 23 Fremont Street, S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

—OR—
VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ore is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

Room 7, 109 California Street, - - - - - SAN FRANCISCO, CAL.
Nov. 6, 1882.

Contains no Nitro-Glycerine or Chlorate of Potash, and is the only High Explosive Manufactured in America that does not contain these Dangerous Ingredients.

Price of Tonite Materially Reduced for 1883.

TONITE POWDER CO.,

No. 327 Pine Street, - - - - - SAN FRANCISCO.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS
All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

- NO. 1.—The most Powerful Explosive Compound now in use here.
- NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
- NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much harder. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same.

Number 7.

Cleavage of Minerals.

This is the property possessed by many crystallized and crystalline minerals, of splitting in certain directions more readily than in others; affording shining surfaces, sometimes curved, but usually plane, called cleavage planes. These cleavages are spoken of as perfect when very smooth, less perfect or imperfect when the new surfaces are somewhat irregular. Sometimes cleavages are spoken of as highly perfect, very perfect, perfect, imperfect and very imperfect. Thus, calcite has a highly perfect and quartz a very imperfect cleavage.

The cleavages are usually parallel to the faces of one of the simpler "forms," consequently they render great assistance to the crystallographer by giving him certain fixed points to start from in "reading" a crystal.

The student should obtain specimens of such easily cleavable minerals as galena, fluor, blende, calcite, etc., and endeavor to obtain from them the different cleavage forms. Thus, from fluor he may get the octohedron and acute rhombohedron, from galena the perfect cube, from blende the rhombic dodecahedron, and from calcite the rhombohedron. By laying the mineral upon a thin cushion or leather pad, placing the edge of a stout knife so as to coincide in direction with the plane of cleavage, and striking the back of the knife sharply with a light hammer, very good cleavage forms may be got without injuring the surfaces already existing.

These false cleavages are sometimes, and more properly, called planes of union. They are formed when two or more crystals increase so as to come in contact. In such cases there is a sort of adhesion, but the compound mass breaks more readily between the crystals than elsewhere. As the broken surfaces so produced are often smooth and shining, they may be mistaken for true cleavages. They may, however, be easily distinguished, since with a true cleavage other lamellae may be readily split off parallel to the first one produced, but this is not so with false cleavages.

The cleavage of rock is frequently quite a distinct phenomena to that of minerals, but sometimes it is determined by the prevailing directions of the constituent minerals. Thus in mica schist the plates of mica have usually a prevailing direction, parallel to which the rock splits readily. In like manner, in many kinds of granite, the felspar crystals have a prevailing direction, which determines the "cleavages" of the mass.

The Ohmen Engine.

We give an engraving on this page of the "Ohmen high-speed engine." These engines are rated in power to run from 300 to 700 ft. of piston speed per minute with or without cut-off. They are made by W. H. Ohmen, of 109 Beale street, in this city, who claims for them economy and durability, and at a great reduction of former prices. In fact, he says he will guarantee his 10x12 engines to do as much work as any 12x24 engine on the market. The Myers' cut-off is used, when any is applied. The engines are made from 6x7 and 8 to 12-horse power to 12x12 and 35 to 80-horse power. The smallest size weighs 350 lbs., and the largest 3,500 lbs. The larger sizes can be furnished with disk crank instead of center crank, if desired.

The Dutch Government will introduce in the Chambers a bill for the demonization of 25,000,000 florins in silver coinage.

The Davidson Wheel.

What are commonly known as hurdy-gurdy wheels are great favorites on this coast, more especially for running the hoisting derricks, so commonly seen in the mining region. We illustrate herewith one of this class of wheels, which was patented this month through the MINING AND SCIENTIFIC PRESS Patent Agency, by R. N. Davidson, of Weaverville,

central discharge turbine. The cut shows the front or discharge side, while the evolved dotted lines show the shape of the buckets coming to a point near the center, caused by the back side of the wheel being concave, thus bringing its apex near the plane of the front side. It also shows the nozzle of the hydraulic pipe near the lower edge of the wheel.

This wheel is well adapted for a country which is well supplied with small mountain streams;

Trinity county. He calls it the "Davidson Turbine or Hydraulic Water Wheel." He does not claim it to be far superior to all other wheels, under all circumstances, but has tried to supply a want long felt, namely: a cheap, simple, durable and easily-managed water wheel, that can

be adapted to all kinds of work on the farm, in the dairy, and the running of all manner of small machinery as well as the largest mills. There is no power as cheap as water power, or any which can compare favorably with it.

This wheel can be made of any required size, from a few inches in diameter, for running a sewing machine or churn, to four or five feet in diameter, for running the largest quartz and lumber mills. They are cast in one piece, without any bolts, slides or other loose parts to get out of order; no tight casing is required, nor is any heavy frame necessary to set them in; can be run horizontally or vertically; are easily moved from place to place, if desired; can be made to run either way; two or more can be put on the same shaft, or two or more nozzles can be turned on the same wheel, if more power is needed, or more water is to be used.

The wheel is constructed partly on the hurdy-gurdy order, but is more properly a hydraulic

even a fair spring at an elevation of 40 or 50 ft. can be made to do all the power work for a moderate farm, such as thrashing, pressing hay, cutting or grinding feed and apples, sawing wood and much other like work. As the power acquired is in proportion to the height of the head it will be seen that a small wheel with a small stream will give quite a large horsepower.

The wheels are well adapted to vertical shafts, and for a cold climate, as they can easily be kept free from water when not in use. They are more particularly adapted to a hilly country where the streams are small and have great fall, as a high head can there be obtained at small expense. For running of a hoisting derrick, so much in use in the mines of the Pacific Coast, from Mexico to Alaska, this wheel excels on account of its compact form and the ease with which it can be attached, as well as the great amount of power which it can certainly be relied on to furnish. Another great advantage is that the wheel cannot clog and will not be injured by muddy water.

WILLIAM MCGRIEVEY, an old rock foreman, known to railroad builders throughout the coast, was killed several days ago on the Northern Pacific at Weeksville.

THE DAVIDSON WATER-WHEEL.

Horses Underground.

It is not proposed here to speak of that style of geological horse which balks the hopes of expectant stockholders so often by coming into the ore body so inconveniently, but of the patient animals employed underground for hauling cars, etc. A short time since a gentleman named Mr. C. Hunting, spoke before the North of England Institute of Mining Engineers on colliery horses, and gave some facts concerning their feeding and management which are of interest. He stated that two things are necessary to produce condition in horses—hard work and high feeding. The former is never lacking in collieries, and the latter can easily be attained if cost be no object. A sufficiency of oats and hay, with plenty of work, will produce condition, but at a most extravagant cost; but high feeding can be economically attained, and horses may be kept in the highest condition at a cost very much below what is usually incurred for animals doing light work. There are three conditions which render high feeding economical: 1st. The selection of the cheapest but best food; 2d, giving that food in a form most favorable to digestion; 3d, the prevention of waste. The writer gave an analysis of the different qualities of food usually given to horses, and explained that several of these articles of provender possess very different qualifications; some are laxative, and some are constipative; but a judicious mixture can be made which will produce a most valuable food. The object of the larger portion of the paper is confined to showing what the mixture should be, and how it should be changed to suit the ever-varying prices of each of its ingredients without losing its nutritive qualities. Oats alone will not keep hard working horses in condition, nor can any single grain preserve both health and condition. He showed that musty or kiln-dried oats are dangerous. Oats should be sound, sweet, and a year old, and their natural weight should be at least 40 lb. per bushel. Maize is a most valuable article of provender for hard working horses. Cutting and bruising the hay are advocated; and the importance of the frequency and regularity of meals is shown. The writer quoted figures showing that at the principal collieries, etc., where his method of feeding is carried out, there was a saving of £41,114 13s. 4d. in the year 1881; the corporation of Newcastle saved £1,252 15s. in 1881. He also gave a statement of the saving effected over a number of years, varying from £117,455 saved in 31 years at South Hetton Colliery down to £4,227 saved by the corporation of Newcastle in four years; the total saving for 17 establishments amounting to £574,285. The saving in the cost of feeding by the writer's method is not by any means the only advantage or the whole economy effected; for it is claimed that horses do more work per annum, are in better condition and last considerably longer than those fed on any other plan. In the course of the discussion which followed the reading of the paper, Mr. Hunting condemned the use of condiments and spices and the cooking or boiling of food for horses.

It is stated that a contract has been let by the Central Pacific Railroad people to build 25 miles of the branch railroad from Berenda toward the Yosemite valley. The road will follow up the Chowchilla, and the division to be contracted for is to be completed by May 1st, in time to accommodate the Yosemite travel this season.

A New Amalgamator.

A. C. Bowen, of Michigan Bluff, Placer county, has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency, what he calls a "disintegrator and amalgamator." The apparatus is supported on a framework. There is a horizontal driving shaft with fast and loose pulleys on the outer end and a bevel gear upon the inner end to engage a similar gear which is fixed to a vertical sleeve. Upon this sleeve-shaft is secured a horizontal wheel with slotted arms and upon one of these arms is a standard, between the upright of which a beveled pulley or roller revolves.

The pan is made with a curved concave interior, the outer portion of which is slightly depressed to form a channel for a ball to travel in. The pan is centrally supported by a ball and socket-joint so as to permit a universal motion around it; or an equivalent universal joint is made by means of a stem projecting downward from the center of the pan and flattened at the lower end. This end is forked and fits a similar loose fork upon the upper end of a vertical shaft below.

The outer part of the pan rests upon a beveled roller which is high enough to give the pan considerable inclination to one side, and as the horizontal wheel or disk is caused to rotate by the action of the bevel gear below, it carries the roller around beneath the rim of the pan, thus alternately lifting every portion of its periphery and giving it the rolling motion desired. The position of the roller beneath the pan may be changed, so as to increase or diminish the motion.

From the center of the pan a pointed shaft extends upward, and is connected by a link with an adjusting screw, extending upward to the top of the framework where it is operated by a nut or otherwise, so as to increase or diminish the meeting angle at the joint in the rod. The jointed rod keeps the pan in place during its movements and prevents its being upset during the rolling movement which is communicated to it by the roller beneath the edge of the pan. The material being then run into the pan while the latter is given its peculiar rocking or oscillating motion by means of the roller and wheel, the ball or balls will roll down the inclined or peripheral channel so as to remain at or near the lowest point, and the material, together with the mercury, which has been placed in the pan, will be thoroughly incorporated and amalgamated.

New Cut-off-Valve Gear.

Mr. Eugene O'Neill, chief draughtsman at the Union Iron Works, in this city has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency, a new form of cut-off-valve gear. Mr. O'Neill has made several important inventions in that line. The steam inlet valve and exhaust valve are operated by peculiar mechanism fully described in a patent issued to this inventor May 26, 1880, and the present invention is designed to provide a means for regulating the point at which the steam is to be cut off, and the speed of the engine governed.

The invention relates to an automatic cut-off for engines, which is operated by a governor or by air, water or steam pressure. It consists in the combination of a valve mechanism and valve tripping devices with a governor or with a cylinder within which a piston is moved to actuate the tripping arms by which the steam valves are released, so as to regulate their point of cutting off and the amount of steam which will be let into the cylinder at each stroke.

The eccentric by which the valves are opened and the one by which the cut-off is operated, are fixed to a shaft which extends parallel to the cylinder at one side, and is driven by a bevel gear from the main engine shaft. The cut-off mechanism consists of a rocker-arm, which is oscillated so as to trip the lever-arm at the proper time, and the change in the position fixes the time.

In his drawing, Mr. O'Neill shows a rock-shaft supported parallel with the cylinder and oscillated by means of an eccentric. Crank arms are fixed to it at each end, and these are united by a loose shaft, upon which other crank arms are fixed. The rocker arms are suitably connected with a movable sleeve upon the governor spindle, so as to be actuated by the movement of the governor; or they may be con-

nected with the piston of a small supplemental cylinder, which is operated either by the pressure of steam in the boiler which supplies the engine, or by the pressure of air from the receiver, into which air is being forced by the engine, or by the pressure of air from a receiver or an accumulator, which is supplied by the engine.

A weight is fixed upon an arm extending downward and outward diagonally from the shaft which forms the fulcrum of the lever. When the piston raises the lever and then turns the fulcrum, it will also raise the weight, and when the pressure upon the piston decreases, the weight acts to force the piston down and return the parts to their former position.

The weight prevents any sudden changes by its inertia, and its power increases as the piston is raised, because it is carried farther from a perpendicular. The lever has a handle by which it and the connected parts may be moved independently of the pressure cylinder or governor. A set-screw serves to clamp or hold the piston at any point, so that the governor may set the cut-off at any desired point independent of the automatic regulating device. Mr. O'Neill is, of course, aware that a piston running in a cylinder under the pressure of steam, air or water, and connected with the valve-tripping or cut-off mechanism of an engine by intermediate mechanism, is old. It is in the details of construction and operation that Mr. O'Neill claims his patent.

An Inventors' Institute.

The "Inventors' Institute of California" has been organized in this city. The officers are as follows: N. W. Spaulding, President; Daniel Buck, Secretary; First National Gold Bank, Treasurer; and A. B. Smith, Manager. The Directors are N. W. Spaulding, Columbus Waterhouse, E. P. Flint, Daniel E. Hayes and Ira P. Rankin. Perhaps the object can best be stated by quoting as follows from the circular:

The objects of the Institute are to sell and dispose of patent inventions of all kinds in this State and elsewhere, either in town, country, manufacturing or shop rights, or whole State rights, or the entire patent at one sale, or upon royalty, according to circumstances. The Institute making a specialty of selling and disposing of patents and patent rights, inventors and patentees can dispose of their inventions by and through the facilities afforded by the Institute, at greater profit and advantage than through private parties. Creditable and useful inventions will be placed before the public by advertising, circulars, agents, etc., so as to bring them to the notice of purchasers. Private parties will be sought out and solicited personally, or through correspondence, to buy particular inventions. Agencies will be established in the Eastern States and elsewhere, through which the Institute will be enabled to sell inventions expeditiously and profitably. Extensive correspondence will be carried on and solicited with parties interested in patent matters, and who use or manufacture special inventions, and every means will be employed by the Institute to extend its resources and influence so as to furnish the very best facilities to patentees and inventors for disposing of useful and meritorious inventions in this State and elsewhere, at profitable and satisfactory prices. The Institute will undertake the sale of inventions upon a commission from 15 to 25 per cent., payable out of the proceeds of sale. It will advertise the invention in a proper manner, and will endeavor, by all fair and honorable means, to obtain the best price therefor. Extra advertising can be agreed upon at reduced rates, and circulars prepared and printed as may be agreed upon.

The rooms of the Institute are located at 321 California street, and are commodious and central. In the exhibition rooms, connected with the Institute, models of inventions will be displayed, and explanations thereof will be cheerfully given to visitors and others. Inventors, patentees, and the general public, are cordially invited to visit the rooms at any time. Information respecting patents and matters relating thereto will be cheerfully given. Periodicals upon patent matters will be found at the room, and the library of the Institute will be available at all times to parties interested. Patrons of the Institute can have their letters sent to its care, and desks will be provided for their use under reasonable limitation.

If you wish only to exhibit your invention in our "exhibition rooms," you should send model and \$10, which will be the charge for space for one month, and thereafter the charges will be \$5 per month in advance. You will thereby have the privilege of explaining your invention yourself to parties interested, together with the assistance of the Institute in promoting its publicity.

THE BEAR RIVER COMPANY'S CLAIM.—In the case of the Bear River California Extension Placer Company's claim, the Commissioner of the General Land Office holds that placer claims upon surveyed lands must conform with public surveys in all cases, except where it is rendered impossible by previous appropriation or reservation of power of legislation. This particular placer lies within the bed of Bear river for some distance, and the opinion is expressed that it would be unwise public policy to impede the navigation or public usefulness of such rivers by the allowance of a claim of this character. The entry has been accordingly held for cancellation.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and foreign Patent Agency, the following are worthy of special mention:

THE WHEELED VEHICLE.—Wilmer T. Adel, San Jose, Cal. No. 271,294. Dated Jan. 30, 1883. This invention relates to the class of two wheeled vehicles, and to certain improvements therein, having for their object the prevention, as far as possible, of the unpleasant jerking motion which has always been the disadvantage of vehicles of this character. The invention consists of a novel spring connection between the shafts and whatever portion of the vehicle to which they may be attached; in a peculiar frame upon and from which the seat and footboard are supported, and in a cross spring supporting the front of the frame. It also consists of certain details of construction, such as dividing and hinging the seat to swing from the center, and the means for supporting it at the center.

WOOD TURNING LATHE.—Albion I. Sanborn, S. F. No. 271,368. Dated Jan. 30, 1883. The improvement consists of a horizontal bed, having a head and tail stock for holding the wood to be turned. The head and tail stock with the article to be turned are moved forward and back upon the frame and are rotated at the same time, so that the article will be subjected to the action of peculiarly constructed revolving cutters as it passes beneath them. In connection with this, the inventor employs a back rest with a cam and roller, by which the rest is made to follow the wood as it is reduced in size, and prevent shaking or trembling.

HORSE-POWER.—Edward A. Rix, San Francisco, Cal. No. 271,123. Dated January 23, 1883. This invention relates to certain improvements in horse-power machinery, in which a horse walking in a circle imparts motion to a drum, upon which a hoisting-cable is wound. It consists of an improved means for connecting the levers or sweeps to which the horse or horses are attached with the drum so as to drive it, and a means for disconnecting it from the sweeps, so that the drum will remain stationary, or may be revolved in either direction.

MINING CAR.—Gustav Ohlsen, assignor of part to Edward A. Rix, S. F., No. 270,689. Dated Jan. 16, 1883. The improvement in this ore car consists in a means for mounting the car body on the turn-table or track, by which the car, and especially its bottom, is relieved from the strain of the connecting bolt, and the weight of the ore within it will be supported by supplemental bars, which are secured beneath the bottom of the car, and through which the pivotal bolt passes.

VEHICLE BRAKE.—George R. Duval, Benecia, Cal. No. 271,047. Dated January 23, 1883. This invention relates to certain improvements in brake blocks for use upon vehicles and it consists in certain details of construction. The brake bar is properly supported and has connected with it the levers or mechanism by which it is moved to and from the wheels, and the brakes applied or removed. The brake blocks are fixed to the ends of the bar so as to stand in front of the wheels, and Mr. Duval's invention relates to an improved means of applying these blocks to the bar.

INCUBATOR.—John Peterson, Oakland, No. 271,355. Dated Jan. 30, 1883. This invention relates to certain improvements in incubators, and to a means for maintaining a regular and equable temperature; and it consists of a series of water-containing chambers so formed as to surround the receptacles for the eggs, and radiate heat upon the eggs from above.

STRAW BURNING BOILER.—Joseph Stevens, San Francisco, Cal. No. 271,148. Dated Jan. 23, 1883. This invention relates to certain improvements in steam boilers in which straw is employed as a fuel, and it consists in a peculiar construction of the device by which the straw is fed to the furnace.

RAILWAY CROSSING BARRIER OR GATE.—William B. Morris, San Francisco, Cal. No. 271,102. Dated January 23, 1883. This invention relates to a new and useful crossing barrier or gate for railway crossings. The object of this invention is to give notice at a point where unusual danger exists, and at the same time keep back those who might attempt to cross the track by placing an obstruction in the road.

FILTER.—James Miller, of Oakland, Cal., No. 271,098. Dated January 23, 1883. This invention relates to a new and useful water-filter, and it consists in the arrangement of vessels with relation to each other and their various divisions into compartments. By the special arrangement a superior filter is effected.

BOILER STRENGTH.—A boiler should be strong enough in every instance to sustain five times its working load before fracture to be quite safe, and allow for all the contingencies of ordinary service.

Copper Mining.

The Omega Copper Mining Company of Philadelphia have recently contracted with the Pacific Iron Works, Rankin, Brayton & Co., San Francisco, for one of their famous water jacket smelters to be erected at once upon their mine in the Helvetia district, near Tucson, Arizona. The Omega is a well-developed mine, and gives promise of being one of the most productive and valuable mines in that Territory. We feel assured that this company have made no mistake in the selection of their reduction works. The Pacific water jacket smelters, for both copper and galena ores, have been a most signal success in all parts of the country and with all classes of ores, and we know of no others that can be considered as anything more than an experiment.

In the interest of mining it may be said that no company can afford to purchase any machinery but that of established character and reputation. The Chicago branch of the Pacific Iron Works, recently established, have already, we understand, a large amount of mining work in hand destined to various localities. The establishment of these works is a much needed enterprise and a matter of genuine satisfaction to Eastern mining operators, who are thus enabled to avail themselves on this side of the continent of the practical experience and skill of this well-known firm, and we predict for them a large and constantly increasing trade. All parties contemplating the erection of any kind of mining, milling or smelting machinery would doubtless consult their interest by communicating with them.—*Philadelphia Mining Journal*.

THE Postoffice Department estimates a surplus of \$4,000,000 to \$5,000,000 the next fiscal year, if the two-cent letter postage is unauthorized. It is estimated that there will be little if any deficiency in consequence of the reduction of postage.

Recent Contributions to the California State Mining Bureau.

[Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY G. HANES, State Mineralogist.]

[CATALOGUE.]

4467. Bird's Feather, coated with carbonate of lime—Formation Springs, Idaho. See No. 4468. Peter Decker.
4468. Atom Incrustation, found 10 miles north of Santa Rosa, Sonoma county, Cal. No. 4469. C. W. Frost.
4469. Copper ore, near Murphy's, Calaveras county, California. E. H. Schaeffle.
4470. Chromic Iron, near Murphy's Calaveras county, California. E. H. Schaeffle.
4471. White Lava—so-called—Indurated Volcanic Ash—near Murphy's, Calaveras county, Cal. E. H. Schaeffle.
4472. Sinterite—Near Murphy's, Calaveras county, Cal. E. H. Schaeffle.
4473. Sedimentary Deposit found in digging a well at a depth of 75 feet, near Reservoir station, Placer county, Cal. No. 4474. E. H. Schaeffle.
4474. Copper ore, practically Chalcopryite—Sections 12-13, township 15 north, range 6 east, Placer county, Cal. E. W. Roberts.
4475. Root resembling an owl's head—Found on the beach, San Francisco bay, near Martinez. T. Z. Davis.
4476. Silver ore showing wire silver—Belle of Butte mine.
4477. Copper Ore—Southern Utah. J. R. Seachman.
4478. Mica—New York & Dakota mining company, Custer county, Dakota, Ter.
4479. Section of Asphaltum Pavement, as laid in San Francisco, generally on a layer of soft brick. This specimen was laid on redwood boards. Composition—to 4 squares (400 square feet) 500 pounds of asphaltum, 1 ton of coarse gravel & 15 pebbles of coal tar from the g works, the whole heated 5 hours.
4480. Sandstone—Glenn Mills, San Mateo county, Cal.
4481. Canoeal Coal—West Virginia.
4482. Cellular Lava—50 miles from the Yaqui river, Sonora, Mexico. E. W. C. Morgan.
4483. White Dolomite—Armstrong Wash, San Bernardino county, Cal. This mineral is very common in the Inyo mountains. J. H. Colerich.
4484. Fossil Bone—Santa Cruz Island, Cal.
4485. Copper Ore, principally Chalcopryite Bullion district, Plumas county, Cal. Wm. E. Ward.
4486. Copper Ore, Oculocite—Entrance mine, Bullion district, Plumas county, Cal. W. E. Ward.
4487. Impressions of fossil leaves in shale, overlying coal or lignite—East of the base of Mount Hamilton, Santa Clara county, Cal. J. R. Seachman.
4488. Rock specimen, silicious, but probably changed from pisolite; an interesting specimen which should be carefully studied—Caucasian, Grant county, Oregon. F. Harvey M. D.
4489. Bog Iron Ore showing vegetable structure—Lava district, near Lost river, Idaho. A. E. Roberts.
4490. Tuff in Bog Iron Ore—Lava district, near Lost river, Idaho. This tuff, being in bedded, seems to prove that the iron ore was at one time plastic. Presented by A. E. Roberts.
4491. Gold in Quartz, cut and polished specimen—Diadem quartz mine, Edman district, Plumas county, Cal. J. A. Edman.
4492. Galena—Muldoo mine, Little Wood river, Alturas county, Idaho. A. E. Roberts.
4493. Lead bullion from Muldoo mine, Little Wood river, Alturas county, Idaho. See No. 4492. A. E. Roberts.
4494. Slag from lead furnace—Muldoo mine, Little Wood river, Alturas county, Idaho. See No. 4492. A. E. Roberts.
4495. Furnace product Muldoo furnace—Little Wood river, Alturas county, Idaho. See No. 4492. A. E. Roberts.
4496. Molybdenite—Vancouver Island, British Columbia. H. Green.
4497. Quartz crystal with included rutile—San Jacinto mining district, Humboldt county, Nev. W. D. Linton.
4498. Lithomane—Lassen county, Cal.
4499. Volcanic Ash—Chalk Bluffs, Nevada county, Cal. near Willow street, Alameda county, Cal. Dr. S. G. George.
4500. Clay from an artesian well 93 ft. deep—San Antonio, Thonito—Quero, Piedmont, Italy.
4501. Dolomite with garnet and clinoclase—Piedmont, Italy.
4502. Dolomite with pyrite on quartz—Traversella, Piedmont, Italy.
4503. Sulphur Crystals—Sicily, Italy.
4504. Calcite Crystals—Traversella, Piedmont, Italy.
4505. Dolomite with pyrite on quartz—Traversella, Piedmont, Italy.
4506. Mangano-calcite on Calcite—Valley of Ala, Piedmont, Italy.
4507. Selenite—Piedmont, Italy.
4508. Orthoclase—Near Lake Maggiore, Italy.
4509. Siderite—Lenticular Crystals—Traversella, Piedmont, Italy.
4510. Siderite Crystals on Magnetite—Traversella, Piedmont, Italy.
4511. Garnets—Traversella, Piedmont, Italy.
4512. Greenovite—Manganiferous Titanite—St. Marcel, Val D'Aosta, Piedmont, Italy.
4513. Barite—Piedmont, Italy.
4514. Dolomite Crystals—Piedmont, Italy.
4515. Epidote with Quartz Crystals—Traversella, Piedmont, Italy.
4516. Mica Crystals—Traversella, Piedmont, Italy.
4517. Epidote Crystals—Valley of Ala, Piedmont, Italy.
4518. Chloritoid—St. Marcel, Valley D'Aosta, Piedmont, Italy.
4519. Magnetite Crystals—Traversella, Piedmont, Italy.
4520. Anglesite Crystals on Calcite—Traversella, Piedmont, Italy.
4521. Dolomite Crystals with Calcite—Traversella, Piedmont, Italy.
4522. Clinoclase Crystals—Piedmont, Italy.
4523. Violan—a variety of Pyroxene—St. Marcel, Val D'Aosta, Piedmont, Italy.

MECHANICAL PROGRESS.

Sawing Hard Steel With Sand.

The practice of mechanics is largely a series of experiments, some successive and cumulative and others isolated and independent. Some months ago a mechanic wished to cut some very narrow slots in a bar of steel that was hammer-hardened, and it was desirable that it should not be annealed and rehardened, because of the danger of disturbing the relative widths of the slots. The workman tried the ordinary saw, or thin rotary milling tool, but found it to be impossible to keep an edge. After many ineffective trials, he recollected having witnessed the sawing of stone with sand urged by sheet iron blades. He substituted a soft iron disk for his steel saw, and, procuring some molding sand, he had the satisfaction of seeing progress made in the obdurate steel. By changing the molding sand for fine quartz sand and using a disk of Muntz sheathing metal, feeding the sand with water, he performed the job in a most satisfactory manner.

Since that time he has experimented with disks of lead and antimony, of copper, plate brass (rolled), sheet iron, and the Muntz metal. He gives the preference to the latter, and has succeeded, by using three thicknesses of the metal, to cut a wide "kef" in slotting more than one-quarter of an inch wide. In a width of these dimension he prefers to score the edge of the disk so that one portion of the cut will be recessed while the other is advanced. The speed must be necessarily moderate—about that of turning iron in the lathe—or the sand and water would be thrown out of the cut before they could do their work.

The quality of the work varies, of course, with that of the cutting material employed, emery and oil not being used advantageously because of their cutting the saw faster than they do the more obdurate material. Quartz sand of various degrees of fineness appears to give the best results, and it seems to be necessary that the disk should be softer than the material to be cut. It is understood, of course, that the disks are not serrated like a circular saw, but are smooth on the edge. Indeed, their action appears to be precisely like that of the toothless blades used in sawing blocks of marble and other stones; they merely push the cutting sand against the material, or perhaps to a certain extent receive and temporarily hold it embedded in their softer material.—*Scientific American*.

THE CIRCULAR SAW CONDEMNED.—In the last report of the French Society for Preventing Accidents from Machines—a society founded under the auspices of the Société Industrielle de Mulhouse—a recommendation is made for the avoidance of the use of circular saws in all workshops where practicable. The following are the reasons for this recommendation: 1. Circular saws are dangerous to workmen. 2. They require more power than other saws. 3. They cut a broader line, and are consequently more wasteful. All of which is doubtless true, but we incline to the opinion that the circular saw will long hold its own, on account of its great convenience. The maul and circular saws are both American tools. The pit and gang gate saws are English, and the single sash saw is of Dutch origin. Up to 1849 very few circular saws were larger than 48 inches in diameter, and none were more than 54 inches, while even 36-inch saws were considered very large and very rarely used. In that year the first saws 60 inches in diameter were brought out, but only two were made during that year.

NEW JOURNAL BEARING.—A recent improvement in linings for journal boxes for car axles, and other purposes, of which Mr. Ferdinand E. Canda, of 52 William street, New York, is the author, consists in taking advantage of the well-known unguentous or anti-friction qualities of mercury. He makes an amalgam of tin in which any of the well-known metals or alloys used for bearings are employed as constituents with mercury.

While the mass is in a plastic state it is subjected to pressure to expel the superfluous quicksilver, and then allowed to harden; the journal box is then ready for use. Plumbago or other suitable anti-friction substances may also be introduced into amalgam if desired. It has been found by experiment that this new journal box metal has superior qualities as an anti-friction substance, and it promises to form an economical, durable, and most useful material for railway axles, and bearings of every description.

PROSPERITY IN MACHINE SHOPS.—The *American Machinist* prints letters from over 40 establishments engaged in manufacturing machinery, engines, boilers, tools and machinists' supplies, representing several States, which tend to show that 1882 was a signally prosperous year, and that confidence in trade for the present year is not lacking. Taken as a whole, however, prices of machinery and tools are lower than they were last January, and the tendency is toward closer competition. Iron and other materials that enter into machine construction are lower than in January, 1882, but as a rule wages of first-class mechanics have not declined.

A NOVEL TRAM CAR ARRANGEMENT.—At a Bavarian exhibition in Nurnberg lately there was shown from Noell's wagon manufactory at Wurzburg, a tram car which does not require switch and siding on meeting another car. The car is kept on the rails by means of a fifth wheel in front of the others, and catching in a groove between the rails. The guide wheel is set in a triangular frame on the fore axle, and when the driver raises this the car readily leaves the rails, and may be drawn over the street pavement in any direction. Such cars have been successfully used in Hamburg and Lisbon. Of course, the leaving the rails involves greater strain for the horses, but this is only temporary and without serious inconvenience.

ECONOMY IN COAL. The *American Machinist* says that one of the means of reducing the consumption of coal under or in a steam boiler, is the keeping of a complete daily record of the amount burned. This does not imply that the saving is made by providing a check on the fireman, but rather that it enables him to gauge different manipulations by the exact results; in others, it affords him a reference in educating himself in his duties. Notwithstanding the expense of providing for weighing and recording the coal burned each day is merely nominal, and will not fail in saving ten times the expense in the majority of instances, it is not done.

TO PRESERVE WIRE ROPE.—The *Scientific American* says that to preserve wire rope against wet and rust and keep it pliable apply raw linseed oil with a piece of sheepskin, wool inside; or mix the oil with equal parts of Spanish brown and lamp black. To preserve wire rope under water or under ground, take mineral or vegetable tar, add one bushel of fresh slaked lime to one barrel of tar, which will neutralize the acid; boil it well, then saturate the rope with boiling tar.

A NEW COMPOSITE PULLEY.—A patent has recently been issued for a composite pulley, formed of a cast-iron hub, a web or body made of paper, pasted and pressed into a solid block of the thickness to give it the required strength, and this web surrounded by a wrought or cast rim secured to the web by means of knees or flanges riveted through the rim and the paper. The claim is made that the rim, having a uniform bearing upon the paper body, is steeper and more even than any iron pulley yet made.

AMERICAN MACHINERY FROM ENGLISH WORKSHOPS.—The latest and most important imitation of American machinery by the English is that of the American locomotive. A prominent firm at Newcastle-on-Tyne has already shipped two engines of the American type to Newfoundland, for use upon a new railway just opened there, and a third is now being finished for the same destination.

By the use of hollow steel shafting, which is now generally introduced in Europe, even for such heavy work as steamship propeller shafts, the weight is very much lessened in proportion to the decreased strength. A 10-inch shaft with a hole four inches in diameter, has its weight reduced 16%, with a loss of only 2.56% of strength. A five-inch hole would make the figures 25 and 4.25.

PAPER CAR WHEELS.—Over 30,000 paper car wheels were in service in this country on the first of January last, with a report of only three failures during the year, neither of which caused any serious injury or harmed a single passenger. They are in use on over 150 different roads, and their record, thus far, it is claimed, is unsurpassed by any other make of wheel.

AMERICAN WOOD WORKING MACHINERY.—The superiority of American made wood-working machinery is everywhere acknowledged. The constantly increasing export trade of our leading manufacturers abundantly proves this. The exportation of our wood-working machines, is destined to assume enormous proportions, and those manufacturers who take early steps to secure this trade will reap a rich reward.

FRENCH BAND SAW BLADES. of which great numbers have been sold in this country, are gradually giving way to home-made blades. Our saw makers can now produce as good blades as can be found in the world. As to the band-sawing machine itself, foreign makers cannot approach the American machines.—*The Wood Worker*.

INCREASED USE FOR ALUMINUM.—Now that aluminum can be produced cheaply we will soon find it coming largely into use to replace the heavy iron work of yachts. It is very light and does not corrode. It will even be possible to sheathe a yacht with it. No more galvanized work.

RAILWAY FIRE SERVICE.—The numerous fires which have recently occurred upon railway trains have brought out a railway fire service which may be attached to any locomotive. It is described as a very simple apparatus readily attached and put to work.

Two 90-ft. lathes, said to be the largest in the world, have been made by the South Boston Iron Works. Each lathe contains 600,000 pounds of iron. They are to be used to bore out cannon.

SCIENTIFIC PROGRESS.

Science in Soap Bubbles.

The soap bubble has now come within the reach of science. By means of those gauzy globes many beautiful and interesting experiments have been made at the Franklin Institute during a lecture by Mr. D. S. Holman, actuary of the Institute, on "Some Effects of Light and Sound." The instruments used were the Holman lantern microscope and the same gentleman's later invention, the phonoscope, which may be freely translated into "seeing sound." The former instrument consists of a metal box containing an oxy-hydrogen light, which is thrown at any angle by condensing lenses upon the object to be magnified. This light is reflected off at another angle through the magnifying lens on a screen, where the object is displayed greatly magnified.

The phonoscope consists of a thin metal tube, on one end of which is a thin cap in which a hole one inch square is cut, and at the other end is a large mouthpiece, such as are used on speaking tubes. The soap-bubble preparation is composed of oleate of soda and glycerine, and from it bubbles two feet in diameter and of exceeding brilliancy can be blown. Some of these have been kept 48 hours under glass. The lecturer dipped the small end of the phonoscope into a saucer filled with this preparation, which left a film across the square opening. The cone of light from the lantern was then thrown upon the film and reflected upon a screen through the magnifying lens, making a figure about two feet square.

The effect was beautiful. At first nothing but a gray surface was seen, then gleams of color appeared, and in a moment the whole square was a mass of dazzling brilliancy which would have put to shame any kaleidoscope ever made. Every instant the beautiful picture changed; now a wonderful design in reds and yellows, looking like a tea store chromo of an Italian sunset; then shifting to a swarm of peacocks' tails, or a pantomime transformation scene struck by lightning and as suddenly changing to a sombre view in blue and purple, or a rainbow dancing a waltz. After showing several of these pictures, the lecturer proceeded to show the effects of sound upon the soap-bubble. A couplet was sung into a phonograph, the mouthpiece of which was placed against the mouthpiece of the phonoscope, and the crank was turned. As the sound issued forth, a curious effect was produced upon the picture. Geometrical figures in black appeared upon it, small and distinct when the notes were high, large and less clearly cut when the notes were low. Around and among the black figures whirled the ever changing colors, red, blue, green, yellow, in all their varying shades, melting into one another too quickly for their blending to be followed by the eye. Human voices also sang to the soap-bubble, and with equally curious results. It is proposed to exhibit this experiment on a very large scale as soon as the new lantern microscope, now being made for the institution, is finished.—*Philadelphia Record*.

HUNGER AND APPETITE.—Dr. Fournie, the French physiologist, distinguishes between hunger and appetite by describing the former as a general desire for food, no matter of what kind, while appetite is the feeling of pleasure which results from the gratification of that desire. This is proved by the fact that often, when we are not hungry, appetite comes while we are eating, or at the mere sight and smell of some favorite dish. The question as to where the seat of the feeling of hunger is, has been much discussed by physiologists. Leven asserts that it is not known at all, while Longet and Schiff believe that it is diffused through the whole body; but this latter view is disproved by the fact that in some diseases people waste away without ever having the slightest feeling of hunger. Dr. Fournie's theory is this: When meal-time arrives the glands of the stomach become filled and distended, and ready to accomplish their function of digesting the food. But if food is not introduced, they remain in this distended condition, and the result is the uneasy feeling we call hunger. Excellent proof of this theory is afforded by the habit of some Indians of eating clay to appease hunger. The introduction of the clay is followed by the discharge of the glands, and the sensation of hunger is arrested.

A HEAVY BRAIN.—It is well known that, although many distinguished men have had very large brains, these have been occasionally equalled by the brains of persons who never displayed remarkable intellect. Another illustration of this has been lately published in the *Cincinnati Lancet*, by Dr. Halderman, of Columbus. A mulatto named Washington Napper, aged 45 years, recently died in the hospital at that town, in consequence of paralytic infection due to an abscess of the thigh. His brain was found to weigh 68½ ounces, nearly 5 ounces more than the famous brain of Cavier. His height was six feet; his limbs are said to have been ape-like in length, his head was massive, lips thick, lower jaw prominent, but his forehead large and well developed. He had been a slave until the year 1862, and had never been regarded as particularly intelligent. He was illiterate, but is said to have been reserved, meditative and economical.

The Scientific Argument for Theism.

Whatever may be said against science and scientific men, as being, in the opinion of some good Christian people, hostile to the doctrines of Christianity, certain facts have been adduced as the result of scientific investigation that lead directly and logically to a faith in a Supreme Being. There was a time, so science teaches, when the earth was a molten mass, a globe of incandescent matter, upon which, or near which, life was an impossibility. There are, doubtless, some germs that are hard to kill; but in such a heat nothing great or small could retain for an instant the least vitality. How, then, was life introduced upon this planet? This question may be asked independently of all ideas or theories in regard to evolution. Life may have begun with a germ so infinitesimal and simple that protoplasm would be a gigantic compound in comparison, and yet the answer would necessitate the admission that some creative agent more potent than matter has been at work. The answer, to be at all satisfactory, necessitates, in short, the existence of a spiritual, intelligent force. Science leads us up to this. There is no escape from this conclusion. It matters not whether we call this force by one name or another; in the last analysis it is God, the Supreme Being, who is the great spiritual force that has always been recognized in some way by human beings from the earliest historic period to the present time. Because we cannot understand how a spirit can act on matter, there is no valid scientific objection in the way of our acceptance of the fact. There are a great many facts which science accepts which it cannot explain. The only question is, does the evidence require that we should accept it? Here are phenomena that nothing we know of in nature can explain, and which, furthermore, are inexplicable on any other than the spiritual hypothesis. Scientific men are therefore called upon to admit the existence of such a spiritual force in nature, that began to act in the production of living things some time after the earth became, by cooling, a fit abode for them. D. L. PECK.

Still Another New Gas.

Mr. Love, in the *Sanitary Engineer*, gives an account of the purpose of a new gas company recently organized in New York with a capital of \$2,000,000.

The company holds three patents issued in 1880. These patents are similar in most particulars, and relate to a process for producing hydrogen gas. It is proposed to decompose, by means of highly heated caustic lime, a mixture of steam and naphtha vapor, or other gaseous substance containing carbon. The mixture of steam and naphtha vapor is first passed through a superheater, after which it enters the converting furnace. This consists of an inverted V-shaped chamber, which is filled with caustic lime through the opening at the top. The patent states that the "furnace is made in two parts, with the object of having one portion cooler than the other."

The contents of this chamber must be heated to a high temperature by gas from a separate generator. This done, the mixture of steam and naphtha vapor is allowed to enter at one end, which is supposed to be the hotter part, and, passing through the lime in the first arm of the chamber, is decomposed with the formation of hydrogen and carbonic acid. "This carbonic acid is subsequently taken up by the lime in the cooler portion of the double furnace, the lime in the first portion being too hot to enter into combination with carbonic acid and form carbonate of lime."

When the temperature of the lime becomes so low that the decomposition is not effected, the flow of steam and naphtha is diverted into another similar furnace, the carbonate of lime in the chamber is rendered caustic again by contact with combustible gases from the separate generator. In this way the process is intended to be continuous—the same lime acting over and over again without removal from the chamber. Indeed, the patent states as the most important improvement of the process the reconversion of the carbonate of lime into lime. It is also claimed that "heated brick or other similar substance" will not take the place of the lime in the decomposition of the gaseous mixture. With lime the resulting products are hydrogen and carbonic acid, while with the other material hydrogen and carbonic oxide would be produced.

HOW TO STOP THE SULPHURIC ACID.—*Knowledge* says that Dr. Jule has been experimenting, with a view to counteracting the bad effects produced by the sulphuric acid, which the combustion of ordinary illuminating gas causes in sufficient quantities to destroy the binding of hooks and to tarnish the lettering on their backs, besides, of course, vitiating the atmosphere so much that the health of the person breathing it is injured. He suspended two plates of finely perforated zinc, one three and the other twelve inches above the burner. At the end of three months the lower plate showed an accumulation of the ordinary brownish-black deposit and a furring of sulphate of zinc, but the upper plate was only slightly affected. The inference from this examination is that a single plate of perforated zinc, about a foot square, placed over a gas jet is sufficient to retain most of the noxious emanations.

those of the Banderita, it was allowed to fall into the hands of procrastinating until there are but few left to certify to its early history or merits.

NEVADA.
Mining Matters.—Grass Valley *Chronicle*, Feb. 16: "There is the expectation that there will be more activity in quartz mining in this district the coming summer than there was reason to expect a few months ago. Some of the prospecting mines which have suspended during the winter months will resume operations, while there are rumors, for which there is some basis, of one or more old mines starting up. There are also several bonding operations of good properties being in course of negotiation with a view of putting them into new and stronger hands, so that it may be said that there is not idleness or indifference as to the opening or development of the quartz resources of the district. There is no field in all California that offers more encouragement for legitimate quartz mining than this. This character of mining has been a successful business here for more than thirty years, during which time many millions of dollars have been extracted, and yet there are many veins that are not fairly prospected on the surface, and a number of properties that have only been superficially worked to the depth of 100 to 300 ft. There is a wealth in the quartz veins of the district that justifies the outlay of a large capital and the efforts and labor of enterprising men. Although much work has been done in the way of exploitation it is merely the beginning of what is yet to be accomplished in this old and reliable gold-bearing region."

ELIOTON FOR JANUARY.—*Transcript*, Feb. 10: Gold bullion to the amount of \$84,000 was shipped to San Francisco last month by mines in this locality through Wells, Fargo & Co.'s express. The shipments for January, 1882, did not equal this amount by about \$20,000.

PLUMAS.—**TAYLOR-PLUMAS MINE.**—*Greenville Bulletin*, Feb. 7: About 30 tons of ore were crushed in the new mill, and from this a partial clean-up was made of bullion to the amount of \$700; the ore crushed was a miscellaneous mixture, taken from all parts of the mine, some from the main tunnel, some from an upper level, and more from the new winze, the purpose being to get near an average of the ore from the mine. It is very tantalizing to have the water fail just when all is ready for going ahead with such an encouraging prospect, but the hard frost and cold clear weather still continues and there is no help for it. In the mine the winze is now down about 50 ft, the many stringers have all run into the main ledge, which is now about 5 ft wide, and looks very well.

SAN BERNARDINO.
SILVER KING.—*Calico Print*, Feb. 3: Work is still progressing in this mine, all the tunnels and drifts having men at work in them. The ore bin at the foot of the large chute, which holds 100 tons of ore, is about full. The road leading to the bin is about finished, and in a few days teams will be hauling the ore to the Oro Grande mill. There have been several good strikes made in the mine lately. The ore taken out now is considerably better than that taken out last summer.

SILVER OBESIA.—This mine has the best external appearance of any in the camp. There is enough ore in sight to reimburse the owners for amount of the purchase money. The car track, chute and bin are about completed, and eight men are at work taking out ore. The mine was surveyed the other day and an application for a patent to the same will soon be made.

SAM HOUSTON, No. 3.—This mine still sustains its excellent reputation. Work is still progressing in the same. Last Monday a vein 28 inches thick was struck bearing rich ore, mostly black metal. In a few days Mr. Johnson will ship to S. B. Holden, of San Francisco, four tons of ore that will assay \$2,000 to the ton. Ten tons of second class ore has just been milled at Sherman's mill that yielded \$202.55 to the ton.

SUE.—Messrs. Sam James and Nels Wager have leased the Sue mine, situated above the falls in Wall Street canyon, and are at work developing the same. They are running a cut into the ledge, which is a strong one, containing spar, and from which they have taken some very rich ore. We saw some specimens that assayed as high as \$7,000 per ton. They claim that there is a large body of ore there that will yield away up in the hundreds.

ANOTHER SALE.—Charles Morris and Richard Wiseman, who owned a third interest, each, in the Dragon No. 1, have sold their interests in the same to Wm. Raymond, getting a good price. They will now put men to work on the road and complete the same to their other mines, thus enabling them to develop the same with much greater ease than heretofore.

SHASTA.
FRENCH GULCH.—*Cor. Redding Independent*, Feb. 9: The quartz mines are all in a progressive way—rolling out tons of ore. Mr. Shafter has recently intersected a lode in a long and deep tunnel he has been driving, at a depth of 250 ft, that will make one's palms itch and mouth water. There is a sale of mining property in progress in this neighborhood to parties resident for good-sized figures. The Gibson Bros. are raising the working force in the mine on Deadwood. Work is going on in the New Brunswick claim, the dry winter being very good for prospectors.

SIERRA.
SCALES DIGGINGS.—*Cor. Sierra Co. Tribune*, Feb. 7: In the mine but little work has been accomplished owing to the cold and freezing weather. The Cleveland company have been working half days for the past three weeks. A slide of bedrock occurred at the mine to-day which completely blocked the mouth of their new shaft. However, Supt. Bean says the accident will only occasion one day's delay. The Fairplay and Union Hill companies commenced washing to-day, but if the cold weather continues they will soon close down again. The Poverty Hill Co. are washing. Two men of this place have been running ahead the tunnel at the Lucky Hill company's claim for the past three weeks.

SHUT DOWN.—*Nevada Transcript*, Feb. 9: A report reaches here that work has been suspended at the Marguerite mine near Sierra City for the following reasons: Two of the Bostonians heavily interested in the property recently came out and upon their arrival instructed Supt. Deidesheimer to reduce the scale of wages. This he said he could not do,

whereupon they would make a start by cutting down his pay. He immediately resigned, and the men working in the mine followed suit as soon as they heard what was going on. It is stated that an effort will be made to get miners in this locality to go up and take the places of those who quit. The Marguerite has been splendidly managed from the start, and in addition to paying off the indebtedness \$49,000, we believe incurred in starting it, has yielded large dividends to the stockholders. It will be unfortunate indeed if any mistakes are made now that may interfere with its future prosperity.

TUOLUMNE.
LEASED.—*Tuolumne Independent*, Feb. 7: The Kincaid Flat Mining Co. has relinquished to Michael White the exclusive privilege of prospecting and working the property of the Company, for the term of four years, from and after the 1st day of January, 1883. White to have the privilege of using any timber growing upon the ground, for his mining purposes, and to have the privilege of removing any improvements he may put upon the ground, and to have three-fourths of the gross proceeds of his labor, and he is not to interfere with any gravel claim upon the ground. White is to send to the representatives of the Company, by express, to San Francisco, all the gold he may take out of the claim, and they are to return to him the three-fourths of gold to which he shall be entitled.

Nevada.
WASHOE DISTRICT.

UNION CON.—On the 2000 level the east crosscut joint with the Sierra Nevada is being pushed forward at the rate of about 20 ft per week in a favorable vein formation. It has yet a considerable distance to go to reach a point where ore can be looked for. The east crosscut on the 2000 level, joint with Mexican, is in a formation that shows many promising feeders of quartz. The pumps in the Union shaft will be started up on Tuesday. The ground both on the 2700 and 2900 levels is now pretty well drained out, and in crosscutting there will be but little trouble with water.

SIERRA NEVADA.—The north lateral drift on the 2900 level is being advanced at the rate of about 20 ft per week in a favorable formation. The east crosscut on the 2900 level, joint with the Union Con., is also being driven ahead at the rate of about 20 ft per week. It is in vein material that shows some quartz.

MEXICAN.—The joint Union Con. east crosscut is still being advanced in a formation that contains many stringers and feeders of quartz. At the joint Ophi winze guides are being put in for a second line of cages. These cages will be in operation the first of next week, when a crosscut will be started east from the station at the 3100 level. The new pumps at the Union shaft will be running next Tuesday, when crosscuts may be started at several points on the 2700 and 2900 levels. These levels are now pretty well drained out.

HALE & NORCROSS.—The main north drift on the 2600 level, joint with Savage, is being advanced at the rate of about 40 ft per week. It is passing through a favorable vein formation that contains numerous feeders of quartz that give good assays.

OHIER.—Guides are being put into a second compartment of the joint Mexican winze from the 2900 down to the 3100 level. This work will be completed and the cages running the first of next week, when a crosscut will be started east from the station at the 3100 level.

NORTH GOLD & CURRY.—Sinking the shaft is making rapid progress. The material encountered continues to be vein porphyry, with frequent stringers of quartz and seams of clay.

UNION SHAFT.—The new pumps will be in and running by Monday or Tuesday, when crosscutting may be commenced at several points in the Mexican and Union Con. mines without fear of trouble from water.

SAVAGE.—The north drift on the 2600 level, joint with the Hale & Norcross, is being advanced at the rate of about 40 ft per week. It is in ground that carries many feeders of quartz that gives good assays.

ALTA.—The drain drift to connect with the south branch of the Suro tunnel is being pushed forward very rapidly. The completion of this work will double the capacity of the Alta pumping machinery.

GOLD & CURRY.—On the 2500 level the west crosscut is being pushed forward through vein porphyry, in which are beginning to be seen frequent seams of clay and quartz.

YELLOW JACKET.—The old upper levels continue to yield a considerable amount of good milling ore. A considerable amount of work in the way of prospecting is being done.

CALIFORNIA.—Good progress is making in the main south lateral drift on the 2900 level. The ground passed through is the usual vein porphyry.

SCORPION.—The east drift on the 500 level is still being pushed across the vein. As yet no sign of the east wall has been found.

POTOST.—The ground through which the main south drift on the 2600 level is passing continues to be dry and favorable.

ANDES.—The drifts are showing a considerable amount of quartz, with occasional bunches of low-grade ore.

CROWN POINT.—Are still extracting a considerable amount of low-grade ore from the old upper levels.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, Feb. 10: The contemplated drift from the bottom of the winze from the fifth shaft level, has been started and has reached a depth of 14 ft. Crosscutting from this drift will soon be commenced toward the footwall of the ledge. Crosscut No. 2, on the fifth shaft level, has been advanced 13 ft, being in the same formation as at the time of the last report; its total length is 46 ft. Stopping a nice vein of sulphuret ore, about a foot in width, still continues above the fifth shaft level. The ore in the stope above the fourth shaft level has improved materially, being about 2 ft in width, of fine yellow chloride, with every indication of widening as the work on it progresses. The daily yield of ore is about 67 tons, which mill No. 2 continues to handle well. The total amount of bullion shipped during January was \$80,197.29, with \$17,207.37 on account of the current month.

MOUNT DIABLO.—The stope above the drift connecting winzes Nos. 1 and 2 shows about a foot of \$70 ore. Some \$60 ore is being stoped from a wide ledge of low grade ore in winze No. 1, below the

third level. Winze No. 2 shows 18 inches of ore assaying \$100 per ton. The stope near the head of winze No. 2 on the third level, is turning out considerable \$80 ore, while winze No. 4 is yielding some ore of a value of \$90 per ton, from narrow streaks found at that point. The stope above this winze, between the second and third levels, has 18 inches of \$75 ore at its eastern end. The appearance in the stope above the west drift, on the third level, is good and is showing a foot of \$75 ore at its eastern end. The intermediate stope above winze No. 1 has developed from 8 to 10 inches of \$200 chloride ore. A small amount of \$75 ore is being taken from the stope on the second level nearly north of the shaft. A wide ledge formation has been encountered in the stope above the west drift from the Callison winze, containing streaks of \$90 ore.

ESMERALDA DISTRICT.
THE CORTIZ MINE.—*Esmeralda Herald*. We are informed that the stopes of the Cortez are looking exceedingly fine. Yesterday work was being carried on in five of them, every one of which was producing good milling ore. A new body of very rich ore was struck a few days ago. The vein, though small when found, has gradually widened until it is now about 18 inches wide. Who knows but what this will lead into one of those large and rich chambers so common on Silver Hill in '63. Hope it will. The Cortez never looked so well since work was commenced on it as it does now.

OSCEOLA DISTRICT.
REMOVED SALE.—*Ward Reflex*, Feb. 3: There is a rumor afloat that the Monroe and Linton mines in Osceola have been sold. The purchase price is not given.

TAYLOR DISTRICT.
FIDDLE.—*Ward Reflex*, Feb. 6: A number of mines in Taylor district were virtually sold last week for \$50,000, but it was "busted out slick and clean" by the man who had worked the hardest to bring it to a head. Everything was perfectly satisfactory until after the papers were made out, and then he said he didn't want to sell, and this after inducing the purchaser to come all the way from Ohio. Child's play of this character is well calculated to damage any district, no matter how bright its prospects may be.

WATER.—*Ward Reflex*, Feb. 3: We are reliably informed that water enough has been struck in Taylor district to supply that camp.

Arizona.

RICH ORE.—*Citizen*, Feb. 11: Mr. J. W. Canada arrived from the Santo Domingo district yesterday with samples of ore from the Excelsior, Hilo Verde and Turner mines. The mines are owned by the Oriole Co. of Baltimore, of which Col. L. A. Smith is superintendent. The Excelsior has a 4-ft ledge that at the depth of 100 ft assays on the average \$227 per ton. The ledge matter of the Hilo Verde at the depth of 65 ft is but 18 inches wide, but it carries a three-inch streak that assays away up into the thousands. The Turner mine in a 10-ft shaft shows a strong ledge of 4 1/2 ft, enriched throughout with black petanque. The Hilo Verde is especially rich, the ore streak mentioned is pure native silver. Three and a half tons of it have been shipped, and will, in the course of a few days, arrive here en route to headquarters at Baltimore. Another and larger shipment will follow soon. The mines are located about 22 miles south of the Gunsight. Some 40 men have been employed by the company who propose shortly to begin development on a much larger scale. If the ore shown by Mr. Canada yesterday be a criterion to judge by, Santo Domingo district must soon become famous for the great wealth of its ores.

GROOM CREEK.—*Prescott Courier*, Feb. 9: We learn that Mr. Riotte, the eminent mining engineer, who recently visited Groom Creek in the employ of the Arizona Queen M. Co., has submitted his report of inspection to the officers of that company. His examination did not extend beyond the Chicago, the principal mine of the group, owned by this company. He speaks in well-deserved praise of the superintendent, Mr. Marrington, and says of the mine that it is a true fissure, has large bodies of good ore, and is of the opinion that, with an expenditure of some \$5,000 for development work and the addition of some necessary machinery for concentrating and otherwise treating the ores, the mine can be made to yield a net revenue of not less than \$100 per day for an indefinite period to come. The high character of Mr. Riotte as an expert, settles beyond doubt all question of the superior merit of this property, and, as there are a great many mines of the same character in the immediate vicinity of the Chicago, Groom Creek may reasonably be expected to come to the front rank as a bullion-producing district of exceptional richness.

A SMELTER FOR THE WORONOCO CO.—*Tombstone Republican*, Feb. 10: Supt. Fowler, of the Woronoco G. & S. M. Co., informed a *Republican* representative to-day that one result of his recent visit East was the purchase of a 30-ton smelter for the mine under his charge, the machinery being now on the way. A 15-ton working test having been made at the Benson smelting works which gave such favorable returns that it was at once concluded to order the necessary plant. The well-known value of the San Diego mine, the property of the Woronoco Co., is a sufficient guarantee to stockholders that, with the smelter in operation, good dividends are a certainty. Thus one more bullion-producer is added to the camp.

Colorado.

STRIKE ON RED ELEPHANT.—*Georgetown Courier*, Feb. 8: An excellent strike was made last week in the Shenandoah Valley lode, on Red Elephant, consisting of from 4 to 8 inches of fine-grained galena, a sample sack of which milled 372 ounces of silver per ton. The lode is owned by W. H. DuLaney, Geo. W. Dollison, Albert Townsend, and H. C. Metcalf, who are working it by contract. It is opened by a tunnel 400 ft long. The drift has been driven along the side of the ore vein, which has been left standing, and last week a shot was put into it and broke down nearly two tons of ore from which the sample sack was taken. The ore has been uncovered for a distance of 80 ft and holds out well in the breast, which gives assurance that the mine in the future will be a profitable and steady producer.

New Mexico.

CARLISLE DISTRICT.—*Cor. New Southwest*, Feb. 7: This district called the Steeple Rock, but better known as the Carlisle district, is located about 50

miles north of Lordsburg, the nearest railroad station to this place. A day's stage runs to Richmond, which is situated 15 miles south of here on the Gila river. A hack-board and mail wagon comes to this place. The principal mine there is the Carlisle. It is owned by a Chicago company, and is managed by Mr. W. A. Farrish, the well known and renowned mining expert. The vein is 50 ft wide on top, and is a true fissure. It can be traced for a mile on the surface. The ore is a free milling gold quartz, and has a ground-stained appearance. At the bottom of the shaft is found considerable silver. Mr. Charles Ford, a well known Colorado mining man, took 10 samples from every part of the mine last week, and with a pan and blow test he found that the ore ran from \$30 to \$300 to the ton. Mr. Farrish says he has got enough \$20 ore on the surface to run a 20-stamp mill 2 years without sinking. The mine is beautifully located, being only 200 ft above the level of Carlisle creek. A new and handsome Fraser & Chalmers 10-stamp mill is being erected on the mine and is nearly completed. Mr. Farrish thinks he will have it running inside of 20 days. The hoisting works are situated about 30 ft behind the mill and the ore will be carried that distance into the top. The Steeple Rock camp is located about 2 miles east of Carlisle. The chief mine in the camp is called the "Rain in the Face." The owners of this mine have a shaft down on it 90 ft. They have a ledge 4 1/2 ft wide of silver ore that will run about \$200 a ton. Several prominent mining men have examined this property lately, and I think it will soon be sold from what I can hear. The Mayflower district is located about 6 miles west of Carlisle. This is a copper camp and contains several very promising prospects. The camp is a new one, and there has not been much work done as yet.

Montana.

NOTES.—*Butte Miner*, Feb. 7: Although with one exception, the amounts involved in transfers of mining property during January were comparatively small, the large number of transactions indicate a very healthy condition of the market; and the fact that the deal was in every case between residents of the district, who are thoroughly familiar with the value of the properties, is a gratifying evidence of the confidence of our own citizens in the future of the Summit Valley district. There were 26 sales during the month, for which the total prices paid was \$31,977. The largest sale was that of the Mountain View lode to Charles N. Larabee for \$20,000.

ALICE.—The activity which characterizes the operations in the Alice properties indicates that the mine is to be worked for all its worth this year. There is no reason why deep mining in this district should not be attended with as satisfactory results as were derived from the lower levels of the Constock lode, and the Alice company seems likely to solve the question definitely, as to whether or not this is a "surface camp."

MAGNA CHARITA.—The mine has become a bigger property than it was ever expected to be, and it has been found necessary to improve the facilities for handling its immense output. It has accordingly been decided to enlarge the shaft by the construction of a new pump compartment.

MOULTON.—The 3-ft vein uncovered last week by the 300-ft south crosscut, is developing in fine shape and widening with the drift. The ore is finer milling than that of the upper levels.

SHONBAR.—The east drift of the 185 level has advanced 70 ft on the ledge. The character of the ore has steadily improved, and during the past week a fine body of gray and pink manganese rock has been uncovered which assays from 150 ounces upward.

Idaho.

SENATE M. AND SMELTING CO.—At a recent election in New York city the control of this company passed to Edward Mathews and Col. E. Green, Mr. Mathews being unanimously elected President and Col. Green manager of the company. The Senate mine, and the Red Cloud, Chief, Nonesuch and Kid claims constituting the Senate group are all rich and permanent looking prospects, needing only the wholesome management now awarded them for speedy development into highly productive and prominent mines of the first rank on Wood river. During the past season the company has acquired a valuable lime quarry, known as the Scorpion claim, and the Red Cloud, Kid, Senate, Fraction, Nonesuch, Edith and Grey Eagle mill sites, all of which are locations that need only time to prove their worth. The smelting works already completed and in excellent running order, have been proven faultless by a trial run and stand ready for operation, with charcoal on hand for a 3 months' run.

Oregon.

COAL.—*Jacksonville Times*, Feb. 7: D. Reynolds of the Meadows has discovered a large vein of stone coal, which grows better as he goes down upon it. It is now 10 ft wide and the coal is of an excellent quality.

FARMER'S FLAT.—Miller & Kretzer's placer diggings on Farmer's flat, have been provided with hydraulic pipe and a little giant, and a good report may be expected from here if the season is at all favorable.

DISCOURAGEMENT.—Some of the miners are led to work during the warm part of the day, but generally speaking there is room for much discouragement. Should the spring be late, there will still be a chance for a good run.

Utah.

NOTES.—*Salt Lake Tribune*, Feb. 10: The information on which it was said in our mining review this week that the Emma mine, in Little Cottonwood, was shut down, proves inaccurate. The Emma is pushing work actively, and no snowslides are likely to affect it. We learn, also, that in spite of the snowslide which struck part of the Flagstaff surface belonging to the other day, that mine is also being actively worked. Workmen in the Northern Spy mine lately made a rich strike in the north drift on the 150 level. Samples of ore were assayed which showed \$7 in gold, 125 ounces silver, and 43 per cent. lead. A contract has just been let to extend the north drift 125 ft on the 250 level. The Artesian well at the Mingo's shafts has reached a depth of 1,016 ft, all the way through sand and gravel. The tools are still going down in search of bedrock and flowing water.

Mining.

Some brilliant genius in the East has finally decided that mining is a legitimate business; that when a dollar taken from the stubborn rocks costs a dollar in the extraction, still there is a saving, because the gathered wealth of the world has been increased by that one dollar. That is a right sensible view. Had the wise man read the *Tribune*, he would have found that fact out years ago. Moreover, he has "dropped on" the fact that a mining camp is not like any other, that instead of lowering the value of the other crops it touches with new life all the surrounding business of the country. That is another fact which the *Tribune* would have supplied, had he but read. He might have gone further still, and discovered that because of the \$1,500,000,000 in gold and silver which the mines of the West have turned out

bury it in the ground. They pay \$150,000,000 a year easily, because the money flows back among the people, and so it is handled over and over. But suppose it were to be buried or sent to China as fast as it is paid, how would it be in four or five years? There would be such squeezing, such panics, such utter prostration of business, such a depreciation of property and such despair as has never been seen in the New World. For this change the miners of the West have been working, and they should not be forgotten or their work underestimated, for more of the good of it has gone East than has remained in the West.

We hold that mining is the most legitimate work a man ever engaged in. He goes into the desert; from a spot which is worthless, to all appearances, he extracts from the matrix in which for ages it has been sleeping, something which savage and civilized men alike respect and covet; something which is indestructible and rare; something, the value of which is known and respected the world around, and something which in all lands stands for a measure of values, and

tion of its product—to Omaha, where \$700,000 were extracted from it; also, at Bonanza City, the Custer ledge, the giant among American mines, from whose unparalleled outcrop of 200 ft. above the surface four men, during 11 months last year, quarried ore which yielded \$1,100,000, and which has, through a small 20-stamp mill, poured out \$1,400,000 in the last 14 months. They will find at Idaho City a small area of the placer ground of one county which has produced \$20,000,000 in gold—more than a million a year for 18 years—and other larger areas, which in years to come will often duplicate Idaho's total placer yield of \$65,000,000. Silver City, Idaho, they will discover, is the home of the famous Elmore, which, with a small 20-stamp mill, in 30 days has poured out \$500,000, the largest month's yield, I believe, of one mine with a mill of this limited capacity yet recorded in the world. Among the tens of thousands of other quartz veins already found is the Morning Star, whose shipment of 100 tons from Silver City to the Atlantic seaboard, containing \$100,000, is fresh in the minds of at least the owners. A near neigh-

full text of the bill at hand as yet, but have received a brief outline of some of its provisions. It provides for the appointment of seven commissioners by the Governor, two of them to be residents of Mariposa county, and the remaining five to be appointed from the State at large. All are to hold office for four years from date of appointment, except two of the five at large, who are to hold office for only two years, to be decided by lot after the appointment.

The duties and powers are prescribed. They are to have charge of the Yosemite Valley and Big Trees, which belong to the State by virtue of Congressional enactment. They are to be a body with corporate powers. They are to select a suitable person, at a salary not to exceed \$1,500 per annum, to look after the Yosemite Valley and Big Trees and improvements under their supervision. The general intention of the bill seems to be the ousting of the present Yosemite Valley Commission, and if this be done we trust that the reappointment of the useful members of the present Board and their employees will follow. In this way the interests

HONDURAS OR TRUE CHINESE.

in the last 33 years, the face of his native land has been transfigured, and the people have accumulated more property than they otherwise would in 150 years. The speaker at the Pioneer supper in New York the other night said truly that no event since the discovery of America has been of so much consequence, in a material sense, as the finding of gold in California. Nothing less would have made possible what has since happened. Without it the war could not have been fought out; without it the payment of the debt would not have been possible for a hundred years to come, and the prospect would have been so gloomy that repudiation would have followed as it did after the revolution of 1776. The mines of the West have been the leaven of the whole land; because of them New York is swiftly becoming the world's commercial center, and real estate from the Atlantic to this side of the Mississippi river has doubled in value. The men of the East should begin to understand this by and by. They tell us that a wheat crop in Minnesota or a corn crop in Ohio is worth more than the gold and silver crop of the West. We do not desire to dispute the figures, but let them sit down and figure up how things would be if they were forced to gather together \$1,500,000,000 and

with which all reasonable things can be procured.—*Salt Lake Tribune*.

Production of Idaho Mines.

About the headwaters of Salmon, Boise and Wood rivers, in southern Idaho, is a region some 2,500 miles in extent, whose early history horders upon the marvelous. Until three years ago its nearest railroad was from 250 to 300 miles away from the leading mines, and the country was practically unknown. Since then it has had the Utah & Northern branch within 150 miles, and has managed to attract some attention in spite of the Leadville, Gunnison and Arizona stampedes. The Oregon Short Line will go to the head of it the coming spring, and the thousands of miners and others who make a pilgrimage in Pullman cars that way will have something of a surprise. They will find of local note at Atlanta the Atlanta ledge, which, traced for miles on the surface, is from 50 to 100 ft. wide, and has shipped (by wagon 300 and by rail 1,100 miles), a thousand tons—a small por-

LIBERIAN.

bor of the Morning Star, in trying to duplicate this output, fell only \$10,000 short, and added another brilliant achievement to those in mining history, by yielding \$4,000,000—\$1,000,000 for each 100 ft. of depth—in a comparatively brief period.

Along the Yankee fork of Salmon river they will perchance gaze in wonder at the Charles Dickens, whose great ore body is so rich that two men have pounded \$11,000 out of it in hand mortars in a single month. Or the Montana mine, where five men extracted \$80,000 last year in eight months, and shipped ore in 20-ton lots worth \$3,000 per ton. They will be shown thousands of pounds of ore from these mines glittering with the native gold, and worth \$5 per pound. These things come like a revelation from a region much of which is still marked unexplored country on some of our maps.

STATE BOARD OF FORESTRY.—Recently, Assemblyman W. L. Smith, of Mariposa and Merced, Chairman of the Committee on Yosemite Valley, Big Trees and Forestry, submitted a bill in the Assembly to create a State Board of Forestry. We have not the

NEEZANA.

of the State in these grand natural endowments can be well served.

Whether the bill provides for the general encouragement of planting out of trees to take the place of those now being used up we are not informed, but suppose that is left to a special bill on the subject yet to be introduced or to the enactment now in force.

THE SORGHUMS.—A large number of varieties of the plant *Sorghum vulgare* are now coming into prominence in this country, both as a source of cane-sugar and as valuable forage for farm animals. To show some of the characteristics of these new varieties, we take three heads of widely different manner of growth. The new varieties are coming continually from seed, and the well-known tendency of the species toward hybridization is being employed by propagators to secure varieties, with the special characteristics which they deem most valuable. The manufacture of cane sugar from sorghum has been pronounced a promising industry by the National Academy of Sciences, to whom the scientific aspects of the process were referred.

THE ENGINEER.

Engineering Enterprise in Hamburg.

The Senate of Hamburg, Germany, as recently reported in an exchange, have had under consideration a scheme for constructing a tunnel under the Elbe and an elevated railway in that city. The construction of a bridge instead of a tunnel is said to be out of the question on account of the width and crowded state of the harbor, and the author of the project has designed the tunnel of such dimensions as would provide both for vehicles and foot passengers, and a double track railway for freight and passengers. This he proposes to effect by building the tunnel of two stories, the road for vehicles and pedestrians to be in the upper story, and the line of railway in the lower story. The estimated cost of the tunnel and railway is \$6,250,000, and they are to be completed in five and a half years.

With its large ports, its vast docks, its hundreds of vessels arriving from all parts of the globe, Hamburg presents a most lively picture of maritime activity. In front of the principal portion of the town, on the opposite bank, is situated the island Steinweider, which contains a number of docks. Steamships are regularly conveying travelers and merchandise between this island and Hamburg. Hence the necessity of this important engineering improvement.

PROPOSED SHIP CANAL IN CANADA.—Some few years since a proposition was made to construct a ship canal across the isthmus which separates the Bay of Fundy from the Gulf of St. Lawrence, at a cost of \$8,000,000. The project was abandoned; but recently Mr. H. C. G. Ketchum, a New Brunswick engineer, has been before the Dominion Parliament. Last year Mr. H. C. G. Ketchum, a New Brunswick civil engineer, came before the Dominion Parliament with a proposal to substitute a ship railway over the same route, in place of the defunct canal scheme. He obtained a charter and a subsidy of \$150,000 per annum for 25 years, when and so long as the railway should be in successful operation. Mr. Ketchum carried the scheme to London, where he has succeeded in getting it taken up by an eminent English contractor, subject to the favorable report of his own engineer, who is now engaged with Mr. Ketchum in examining the site. If the scheme is carried out, the Dominion will be the first country in the world to possess a ship railway, and probably there is no other country which possesses a site more favorable to its engineering aspects for a perfect railway—that is, a ship railway without curves or grades.

SUBMARINE WORK. It is said that an English firm are engaged in putting into actual practice the Jules Verne's romantic device, put forth in his famous work, "Twenty Thousand Leagues Under the Sea." It will be recollected that his divers are represented by the author as putting on their armor in the usual fashion, and then attaching oxygen reservoirs at the back, going into the water free and independent of heavy air pumps and heavy dragging air pipes. The new English system calls for the manufacture of oxygen and its compression into tanks, which are strapped upon the armor. The carbonic acid of the breath is removed by means of caustic potash, and a fresh supply of oxygen takes the place of that used up by breathing. The diver is, of course, entirely independent of the surface, and can walk about as much at his ease as it is possible beneath the surface of the water, weighted by the usual amount of lead necessary to keep him submerged. The system is one of the most interesting things in its line brought before the public for many years, and submarine work will be greatly benefited by it. No doubt some time will be necessary to practically understand all the details of its working, as the system is not presented as being in a sufficient practicable state to be in every day use away from skillful attendance.

THE WASHINGTON MONUMENT.—Some 40 years ago, when the people of the United States had raised a considerable sum for the purpose, this monument was begun. When the monument had been built to 156 ft. in height the funds were exhausted. Finally the Government took hold and made appropriations to finish the work. But when the labor on it was renewed, examination showed that the foundation was not strong enough for the intended superstructure; but how to insert additional strength under a column weighing 32,000 tons without disturbing its equilibrium or making a crack in its walls, how to remove the dirt below this tremendous weight and insert concrete masonry therein, was a question that required inventive genius and delicate engineering. The difficult work was most boldly and successfully done. A solid body of masonry, about 126 ft. square, and more than 13 ft. in depth, now underlies this tall structure. It ought to have a solid base, for the monument, when finished, will have a total weight of over 80,000 tons. This pillar is now about 350 ft. high, and is rising in mid-air at the rate of nearly 100 ft. a year. From two to three more working seasons will be required to complete it. When completed it will be 555 ft. high.

USEFUL INFORMATION.

PRESERVATION OF BUTTER.—Dr. W. Hagemann has been investigating the cause of butter becoming rancid, which is the immediate result of the liberation of butyric acid. He says it is not the result of butyric fermentation, but is due to the formation of lactic acid from milk sugar, which is present in butter to the extent of 0.5 to 0.6. The lactic acid liberates an equivalent quantity of acids from the glycerides of higher carbon percentage. This, he thinks, explains why summer butter gets rancid more quickly than winter butter, and that artificial butter gives less cause of complaint than natural butter from spoiling.

To preserve butter, one of two methods may be chosen. Either the lower fatty acids are neutralized by caustic soda, which process was perfected by Prof. Adolf Mayer and Dr. Clausnitzer, or care is taken to remove the milk sugar, preventing its decomposition. The decomposition of sugar in cow's butter is caused by lactic acid bacteria, so that the first problem in the preservation of butter is to find some method for suppressing these bacteria.

FOR FENCE POSTS.—A writer in an exchange says: "I discovered many years ago that wood could be made to last longer than iron in the ground, but thought the process so simple that it was not well to make a stir about it. I would as soon have poplar, basswood, or ash as any other kind of timber for fence posts. I have taken out basswood posts, after having been set seven years, that were as sound when taken out as when first put in the ground. Time and weather seemed to have had no effect on them. The posts can be prepared for less than two cents apiece. This is the recipe: Take boiled linseed oil and stir in pulverized coal to the consistency of paint. Put a coat of this over the timber, and there is not a man that will live to see it rot."

CHEESE PREPARED FROM BEANS.—A late Indo-Chinese steamer, arriving at Marseilles, brought specimens of a bean which has long been used by the Chinese and Japanese as an article of food. Not only is it cooked and eaten like other vegetables, but it is made into cheese. By its composition it more closely resembles animal food than any other vegetable known to us, containing much greasy matter and albumen. A trial will be made to acclimate it in our southern departments. In the north it will not grow, owing to the uncertain and changing climate, and the temperature being too low. Besides these advantages, as an article of human food, the husks serve as very good fodder for horses and cows. The cheese made from the Japanese bean has a very delicate taste, much like Parmesan.—*London Daily News.*

TO KEEP THE GRATES BRIGHT.—When a grate is purchased, and you ask how to keep the polished parts as bright as they then are, you will almost always get an evasive answer, for what reason I never could understand. I would suppose that the vendors of grates would be pleased to know that the grates they dispose of would always look clean and bright after they have left their possession. I have, however, discovered a mode for keeping the polished parts of grates perfectly bright, without using an undue quantity of "elbow grease" either. It is simply to take a piece of flannel, moisten it with *coal-oil*, next dip in powdered *emery*, and rub, when brightness will suddenly appear, and the matronly heart will be gladdened.—*Cor. Germantown Tel.*

APPROPS OF aerial navigation, the following singular extract from the discourse of M. de Comberousse, pronounced at the funeral of the late Henri Gifford, will be read with interest: "An intimate friend of Gifford told me yesterday that he carried to the tomb the secret that he had long sought for, and which had revealed itself to his eyes during his last years. He added that our colleague shrank back from his own discovery, and, filled with horror, put an end to his own existence." "In other words," remarks the *Journal of Science*, in a comment on the above, "he saw, at length, that aerial navigation must prove the suicide of civilization."

THE FORMATION OF HAIR.—Each hair is formed of 10 or 12 smaller hairs, which unite at the root and form a hollow tube, somewhat like a very fine stalk of grass, jointed at intervals. The joints appear to overlap each other, as if one small tube were inserted into that which is nearest to it, and so on to the end of the hair. This structure, though invisible to the naked eye, may be made manifest to the touch. Take a hair several inches long, and work it between your thumb and finger, and you will find that it will always work toward the top end, and never (turn it as you will) towards the root end, proving that the rough overlappings are all directed to the top.

KILL YOUR FISH.—A French scientist, explaining why fish eaten in Holland are superior to those eaten in France, gives a hint that may interest fishermen in this country. He says that the Dutch fishermen kill their fish as soon as taken from the water by making a slight longitudinal incision under the tail with a sharp instrument. The French fishermen, on the contrary, allow their fish to die slowly and this slow death softens the tissues and renders them more liable to undergo change.

A HINT TO SMOKERS.—An English working-man, just past the middle age, found that his pipe, which had for many years been a great comfort to him, was beginning to seriously affect his nerves. Before giving it up, however, he determined to find out if there was no way by which he might continue to smoke without feeling its effects to an injurious extent. He accordingly wrote to a medical journal, and was recommended to fill the bowl of the pipe one-third full of table salt, and press the tobacco hard down upon it, as in ordinary smoking. The result was very satisfactory. During the process of smoking the salt solidifies, while remaining porous, and when the hardened lump is removed at the end of a day's smoking it is found to have absorbed so much of the oil of tobacco as to be deeply colored. The salt should be renewed daily.

WASHING harness with warm water and soap soon injures the leather. All varnishes, and blacking containing varnish, are injurious. When harness becomes rusty, give a new coat of grain black. Before applying this, wash the grain side of the leather with potash water, cold, until all the grease is removed. After the leather is quite dry, apply the grain black, and then oil and tallow. This fastens the color and makes the harness flexible and soft. Grained harness can be cleaned by a cloth moistened with kerosene, but should be immediately washed and oiled afterward.

TO REMOVE PUTTY.—Old putty may be readily softened and removed by using a paste of caustic lye, easily prepared by mixing carbonate of potash (or soda) with equal parts of freshly burned quicklime, which has been previously sprinkled with water so as to cause it to fall into powder. This should be mixed with water to a paste, and spread on the putty to be softened. If one application is not sufficient, it should be repeated.

A PAPER WATCH has been exhibited by a Dresden watchmaker. The paper is prepared in such a manner that the watch is said to be as serviceable as those in ordinary use.

GOOD HEALTH.

Tight Lacing.

This is a question, the mere mention of which is "tabooed" in polite society. He who is bold enough to protest against the prevailing fashions, whether of corsets, banded hair or high heels, must be prepared to encounter the frowns of the fairest, and, perhaps, excommunication from all social circles in which he dare exercise the liberty of free speech. It is utterly useless to attempt to convince young women of the evils that later come from lacing. No child is satisfied that fire will burn until his own fingers have been blistered, and, strange as it may seem, it is quite as difficult to convince matrons of middle age, when they have had their forms, from childhood, held in the grip of steel and buckram.

"Were I to leave off my corsets," says one, "I should be limp as a rag. These strengthen and sustain me." Quite right, madam, but why? Simply because you have worn corsets so long that they have appropriated the office that the muscles of the chest were intended for, and these, having nothing to do, have dwindled away or perished, leaving the upper half of your body to be supported by corsets. What nature has no use for, she finally dispenses with. She is generous, but, at the same time, exercises a wise economy, and does not long burden us with useless gifts.

Paralysis of the pectoral muscles is the least of the evils induced by lacing. Long continued pressure on the vital organs impedes their action and deranges their functions. It is a prominent cause of heart disease, consumption and spinal irritation. It is not necessary to be a physiologist to feel a sort of disgust for an abnormally small waist, or a philanthropist to pity its victim. There is something barbarous and repulsive in the fashion of making cripples of Chinese women by lacing their feet. Would it be more humane to make perpetual invalids of them by lacing their bodies?

SCIENTIFIC NURSING.—There is no subject of so much general interest as this, concerning which there is, at the same time, such a widely prevalent ignorance. There are few, especially among women, upon whom will not devolve, at some time in their lives, the care of the sick; fewer still, who will not at some time become dependent upon such care; and it might naturally be supposed that matters of such primary and universal importance as sanitary conditions and the practical application in the sick room of scientific principles would be too familiar to every one to need to be further enlarged upon. But the fact is, it too frequently happens that all the scientific knowledge which ever enters the sick room comes in with the doctor and goes out again with him. This state of things requires to be improved. Knowledge, and that correct knowledge we call science, is just as indispensable to the nurse as to anybody else. It is a great mistake to suppose that all women—even good women—make good nurses. The best intention and the tenderest heart may co-exist with an utter lack of executive ability, and be more than counterbalanced by ignorance and prejudice. Native aptitude gives advantage, but it cannot be relied upon alone. Even

those who possess in the highest degree the natural gift of ministrations which renders them so acceptable to the invalid, would find their power of usefulness very largely increased by a familiarity with what may be properly called the science of the sick room. Physicians are recognizing more and more the importance of hygienic agencies in the treatment of disease, and with this there has come an increasingly urgent call for the scientific instruction and practical training of those who are to take charge of invalids. Science explains the conditions upon which the art of the nurse depends, and lays down principles which cannot be violated without injury; but it is not at all necessary to make a parade of technical language in stating its requirements. *Popular Science Monthly.*

EFFECTS OF TOO MUCH BRAIN WORK FOR CHILDREN.—On April 28th, Dr. Richardson delivered a lecture on "Natural Necessities as Basis of Natural Education," before the Society of Arts, brought forward, writes F. C. S., the following extract, which happened to be a report of the chairman of the evening. Mr. Edwin Chadwick, C. B., to the British Association in 1860, to show what an evil effect too much brain work, without a proportional amount of industrial occupation to support it, has upon young children: "In one large establishment, containing about 600 children, half girls and half boys, the means of industrial occupation were gained for the girls before any were obtained for the boys. The girls were therefore put upon half-time tuitions, that is to say, their time of book instruction was reduced from 36 hours to 18 hours per week, given on the three alternate days of their industrial occupation, the boys remaining at full school time of 36 hours per week, the teaching being the same, on the same system and by the same teachers, the same school attendance in weeks and years in both cases. On the periodical examination of the school, surprise was expressed by the inspectors at finding how much more alert, mentally, the girls were than the boys, and in advance in book attainments. Subsequently, industrial occupation was found for the boys, when their time of book instruction was reduced from 36 hours a week to 18, and after a while the boys were proved, upon examination, to have obtained their previous relative position, which was in advance of the girls."

HOW DIMPLES ARE MADE.—This is the way dimples are manufactured in Chicago, if a reporter of the *Herald* of that city tells the truth: "My arm being bare and the exact spot indicated, he (the operator) placed a small glass tube, the orifice of which was extremely small, upon the spot. This tube had working within it a piston, and was so small that when the handle was drawn up the air was exhausted from the tube and it adhered to the flesh, raising a slight protuberance. Around this raised portion the operator daintily tied a bit of scarlet silk, and then took away his suction machine. The little point of skin that was thus raised he sliced off with a wicked looking knife, bringing the blood. I tried hard not to scream, but it was so unexpected that I had to. Then he bound up the arm, placing over the wound a small silver object like an inverted cone, the point of which was rounded and polished. This little point was adjusted so as to depress the exact center of the cut. Then he told me to go away and not touch the spot until the next day. When I came at that time he dressed my arm again, and this operation was repeated for five days, when the wound was healed. The silver cone was removed, and there, sure enough beneath it was the prettiest dimple in the world! And all I had to pay was \$10."

WHEN IS A PERSON DEAD?—A recent writer in the *China Review* exemplifies the difficulties surrounding interpretation from Chinese into English, or vice versa, by mentioning that simple question, Was he (or she) dead? which occurs so frequently in inquests and other judicial proceedings, admits of a positive or negative reply according to whether the European or Chinese idea as to when death occurs be followed. We believe that a man is dead when he has ceased to breathe, and when his blood no longer circulates; the Chinese consider him still alive while a trace of warmth lingers in the body. The two estimates may thus differ by several hours. Hence, it was that in inquests in Hongkong the time of death formed a stumbling block in almost every Chinese case. The medical evidence would show that the deceased must have been dead when brought to the hospital, while the relatives would swear he was alive at the gate. Subsequent inquiry showed that the general view among the Chinese was that a person is considered to be dead when the body is cold, and not before. It does not speak very well for the Chinese scholarship of the officials of Hongkong that it took about 40 years to discover this important distinction.—*Nature.*

HEADACHE.—Dr. Haley says (*Australian Medical Journal*, Aug. 15, 1881), that as a rule, a dull, heavy headache, situated over the brows, and accompanied by languor, chilliness, and a feeling of general discomfort, with distaste for food, which often approaches to nausea, can be completely removed in about 10 minutes, by a two-grain dose of iodide of potassium, dissolved in half a wineglassful of water; this should be so sipped that the whole quantity may be consumed in about 10 minutes.—*Glasgow Medical Journal.*

TABLE OF CONTENTS.

EDITORIALS.—Cleavages of Minerals; The Ohmen Engine; The Davidson Wheel; Horses Underground, 105. A New Amalgamator; New Cut-off Valve Gear; An Inventors' Institute; Notices of Recent Patents, 106. The Sorghums, 110. Passing Events; American Association of Mining Industries; Miners' New Safety Lamp, 112. Notes from Eureka, Nev.; Mine Timbering—No. 3, 113.

ILLUSTRATIONS.—The Davidson Water Wheel, 105. The Sorghums, 110. Arrangement of Timbers in Staves, 113.

MECHANICAL PROGRESS.—Sawing Hard Steel with Sand; The Circular Saw Condemned; New Journal Bearing; Prosperity in Machine Shops; A Novel Tram Car Arrangement; Economy in Coal; To Preserve Wire Rope; A New Composite Pulley; American Machinery from English Workshops; Paper Car Wheels; American Woodworking Machinery; Increased Use for Aluminum; Railway Fire Service, 107.

SCIENTIFIC PROGRESS.—Science in Soap Bubbles; Hunger and Appetite; A Heavy Brain; The Scientific Argument for Thisism; Still Another New Gas; How to Saponify Sulphuric Acid, 107.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meetings and Dividends, 108.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana and New Mexico, 108-109.

THE ENGINEER.—Engineering Enterprise in Hamburg; Proposed Ship Canal in Canada; Submarines Work; The Washington Monument, 111.

USEFUL INFORMATION.—Preservation of Butters; For Fences Posts; Cheese Prepared from Beans; To Keep the Grates Bright; The Formation of Hair; Kill Your Fish; A Hint to Smokers; To Remove Putty, 111.

GOOD HEALTH.—Tight Lacing; Scientific Nursing; Effects of Too much Brain Work for Children; How Dimples are Made; When is a Person Dead; Headache, 111.

MISCELLANEOUS.—Copper Mining; Recent Contributions to the California State Mining Bureau, 106. Mining; Production of Idaho Mines, 110.

NEWS IN BRIEF—On page 116 and other pages.

Business Announcements.

Dividend Notice—M. & M. Co., S. F.
Dividend Notice—Silver King Mining Co., S. F.
Lithographer and Engraver—G. H. Baker, S. F.

Passing Events.

The most welcome event which has occurred for some time has been the fine rain storm which swept over California this week, bringing everywhere rejoicing and hopeful feelings among both miners and farmers. It has killed off the cold weather, thawed out the ice and done good generally.

Bullion shipments from the mines seem to have fallen off of late, no doubt influenced by the recent cold spell which has spread in every direction. Work is of course retarded more or less in the mining regions under such conditions.

Efforts have been made on this coast to get up a creditable showing of minerals for the coming Amsterdam exposition, and what has been collected will be sent away in about a week from now. Utah, Idaho, Montana and Colorado will be represented, but none of the other mining States or Territories.

We shall next week issue a double edition of the MINING AND SCIENTIFIC PRESS devoted more particularly to the interest of southwestern Nevada.

A SPIRIT thermometer in Butte, M. T., indicated 60° below zero during the late cold weather.

Amalgamating Pans.

The pans employed for grinding and amalgamation present a great variety in the details of construction. Of late, moreover, since many new persons have come into mining as a business, many forms have been proposed which have long since been found of no practical benefit. Since the first "common pan," a very simple form of apparatus, came into use, many inventors have exercised their ingenuity in getting up all kinds of details, mainly to get patents. Each of these forms has its advocates and friends, although of late the one commonly used is called the "combination pan," and is found to answer the purposes for which it was intended perfectly well.

The common features of all amalgamating pans are a round tub, usually of cast iron, but sometimes with wooden sides or wooden lining, from four to six feet in diameter, and about two feet deep, having a hollow pillar cast in the center, within which is an upright shaft projecting above the top of the pillar that may be set in revolution by gearing below the pan. To the top of this shaft is attached, by means of a key or feather, a yoke or driver, by which the muller or upper grinding surface is set in motion. To the bottom of the pan on the inside is fixed a false bottom of iron, generally in sections called dies, or in one piece having a diameter a little less than the pan and with a central hole adapted to the central pillar. This serves as the lower grinding surface.

The muller forming the upper grinding surface is usually a circular plate of iron, corresponding in size and form to the false bottom just described, having a diameter nearly equal to that of the pan, and a flat, conical or conoidal form, according to the shape of the pan bottom. Its under side is faced with shoes of iron or steel that may be removed and replaced at will. The muller is attached to the driver, which is put on and over the central pillar of the pan, and being connected with the interior upright shaft, as described, is thus caused to revolve.

There are various appliances for raising or lowering the muller so that it may rest with its whole weight upon the pan bottom, in order to produce the greatest grinding effect, or be maintained at any desired distance above it when less power or mere agitation are desired. Various devices are also in use for giving proper motion to the pulp, so that when the muller is in revolution the material may be kept constantly in circulation, passing between the grinding surface and running into contact with the quicksilver. Some pans are cast with a hollow chamber at the bottom for the admission of steam in order to heat the pulp, while others employ only "live steam," which is delivered directly into the pulp by a pipe. The operation of the pan consists in the further reduction or grinding of the ore to a pure pulp, and in the extraction of the precious metals by amalgamation with mercury. The amount of ore at each charge varies from 600 or 800 to 4,000 or 5,000 lbs., according to size of pan. The ordinary charge is 1,200 to 1,500 lbs.

An Absurd Proposition.

Twenty years ago if any man in California had prophesied that in 1883 a proposition would be made for the State Legislature to declare the working of placer mines a public nuisance, he would have been considered a lunatic. Yet last week such a thing occurred. A member of the State Senate named Kelly, from Solano, introduced an absurd proposition to that effect. The bill proposes to add two new sections to the chapter of the Civil Code relating to nuisances, as follows:

Sec. 3477. The working of placer mines by the method of mining distinctly known as the hydraulic process, the tailings, debris, detritus or refuse matter of which are carried or suffered to empty or flow into, or which do, either directly or indirectly, empty or flow into any of the navigable rivers or bays of this State, or into any of the principal tributaries of such rivers or bays, is a public nuisance.

Sec. 3478. In actions to abate nuisances described in section 3477 of this Act, where no damages are claimed, or for an injunction or restraining order, to prevent the commission or continuance of acts creating or causing such nuisances, all persons or corporations contributing to the creation, or causes, or continuance of the nuisance complained of may be joined as defendants.

THE Guion Line steamer Alaska made her last passage from New York to Queenstown in 6 days, 20 hours and 33 minutes.

American Association of Mining Industries.

The Commissioners of the mining States and Territories to the last Exposition have organized what is called the "American Association of Mining Industries," which is intended to continue such exhibits in the future, for the purpose of making known the vast mineral resources of the Western States and Territories.

The Association intends to assist in the organization of State and Territorial Associations of Mining Industries, for the purpose of collecting full and reliable statistics of the mines and mining resources of each district in the respective States and Territories, together with characteristic samples of the ores and minerals of each district, the extent and character of reduction works, and the market value of the output of the precious and useful metals, cost of extraction of the ores per ton, and cost of reduction, etc.

It recommends that action should be taken in each State and Territory to secure legislative aid for the erection of State or Territorial museums for the preservation and classification of the ores and statistics collected, and for the publication of catalogues of all ores and minerals collected each year, that are of commercial or scientific value, together with the amount and value of every useful metal or mineral produced in every mining district of each State or Territory and all other facts that have any important bearing upon the various mining industries of the country.

A committee of three was appointed to formulate plans for the collection and preservation of samples of ores and minerals, geological and scientific facts, and blank forms and directions that will ensure uniformity of method throughout the country, in the organization of State and local societies and the work to be performed by them.

The officers of the association are J. Alden Smith, President; J. E. Clayton, Vice-President, and R. A. Kerker, Sec'y. The headquarters are at Denver, Col. The executive committee is composed of J. Alden Smith, L. D. Phillips, E. Y. Naylor, J. P. Flynn and H. L. Thompson. The Directors are as follows: Arizona, T. B. Soren, Prof. J. A. Church; California, Prof. W. B. Ewer, Henry G. Hanks; Colorado, Prof. J. Alden Smith, Capt. L. D. Phillips; J. P. Flynn, E. Y. Naylor, H. D. Thompson; Dakota, J. V. Offenbacher; C. W. Robbins; Idaho, J. L. Onerdonk, H. Z. Burkhardt; Missouri, M. McLellan, L. B. Woodside; Montana, J. B. Reed; Nevada, E. T. George, B. G. Smith; New Mexico, Prof. W. B. Sloan, Dr. Geo. S. Haskell; Utah, O. J. Hollister, Prof. J. E. Clayton; Sonora—Old Mexico, Con. T. Cutler, George Parsons; Wyoming, Gov. Jno. H. Hoyt, Prof. Bailey.

Expositions will be held annually, and therefore to perfect the necessary arrangements as well as the advancement of the mining interests of the country at large, it is deemed advisable by the commissioners to the recent exposition acting in conjunction with the legitimate mine owners, to perfect a national organization of miners of America for the purposes named. The annual fees of membership are five dollars. It may be remembered that there was some dissatisfaction with the management of the Colorado Mining Exposition of last year, and that it was hoped there would be a change if a successful exposition was to be expected this year. As we understand it, this association, of which we speak, is not in sympathy with the management of the previous exposition.

DOUBLE EDITION.—We shall next week issue a double sheet edition of the MINING AND SCIENTIFIC PRESS, and shall devote a large portion of our space to the mineral region of southwestern Nevada. The edition will be very fully illustrated, and will be of interest and value for reference and preservation. A new map of the region will be given, among other things showing the location of all the mining districts of that part of the State.

It is a well-known fact that all coal miners spit black, and that this continues for a month after they have left the colliery; many of them are attacked by a malady which is peculiar to them, caruncular melauosis; a kind of stopping up of the lungs. After 40 years' work, there are few men who do not suffer, and the penetration into the lungs is so complete that if, after 10 years' cessation from work, a miner be attacked with acute bronchitis he sees the coal reappear in his expectoration.

Miners' New Safety Lamp.

There are generally two kinds of safety lamps used in fiery mines. One, like the primitive Davy lamp, is surrounded from top to bottom with a metallic gauze of a greater or less degree of fineness; the other, in order to furnish a better light, is supplied at the base in front of the burner with a short crystal cylinder, suitably protected by thick iron wire, and firmly fastened to the metallic gauze placed above. These two kinds of lamps render undoubted services, but cannot, however, provide complete immunity from accidents. They show the presence of gas but do not prevent explosions. The new Birekel lamp guards against the difficulties. It is so arranged as to not only indicate the presence of gas, but to go out automatically if there is much of it. The Birekel lamp belongs to the species of lamp with a crystal cylinder. It differs from the old lamps by a double case made of tin, which completely covers the metallic gauze. The interior case is fixed to the gauze itself; the exterior case can slide round the interior with a gentle friction. For the admission of air and the emission of the products of combustion of the oil, the two cases are pierced with a certain number of vertical openings made in the tin, parallel to the lines of the cylinder. For the lamp to work, it is evident that the openings of the movable outer case shall correspond to those of the fixed case. This is the ordinary state of things. In this state the lamp burns easily, and gives a good light through the crystal cylinder. The attentive miner recognizes the presence of gas, by signs which are well known to all—the blue halo round the white flame. To avoid all danger, it is sufficient for him then rapidly to turn the movable case. The openings are then closed and the lamp is extinguished. But here again this pre-supposes that the miner watches the lamp and not his work. The danger of explosion is not therefore overcome. But here is the expedient to which M. Birekel has recourse. He has observed that in reducing the width of the apertures, by the partial rotation of the gas to six or seven millimetres, the pure air no longer was furnished in sufficient proportion to maintain the combustion of the burner, as soon as the atmosphere became explosive. Under these conditions, therefore, the lamp is spontaneously extinguished. The danger of explosion is thus seen to be avoided automatically by the lamp itself. At Pechellbronn, France, all the miners have been using this lamp two years, without there having been any accident.

Duty on Quicksilver.

We recently had an article on the question of putting a duty on quicksilver, giving the reasons advanced for taking it off the free list. The following dispatch from Washington shows the action taken: The House yesterday agreed to recommend a duty of 25% on quicksilver. Mr. Page moved that the duty be fixed at 35%, and, at Judge Kelley's suggestion, compromised on 25%. The product had increased from 7,723 flasks in 1850 to 1,197,095 flasks in 1880, although during the last few years the product had decreased, owing to foreign competition. Kelley explained the use of quicksilver in mining, and advocated the imposition of a just rate of duty, which he thought was 25%. Mr. Berry said that while he was not advocating a tariff for protection, he wished quicksilver to have it. He was inclined to favor a lower rate than 25%. He said that every gold mine in California used it, and if the duty were increased in price, every miner in the State would feel it. He wished a fair protection for quicksilver, but not such protection as would increase its price. Mr. Rosecrans claimed that the history of quicksilver manufacturing on the Pacific slope showed that when the duty was taken from quicksilver, most of the small manufactories were ruined, and only four or five of the large companies survived. They made combinations with owners of the foreign product, and prices were increased. Since then the manufacture had been greatly reduced. He said the miners were willing to pay a small tax, as an insurance against big monopolies, by the development of small mines. There would then be more competition, and a reduction in price would follow. Sparks moved to amend Page's motion, by fixing the duty at 10%. This was voted down. Mr. Berry voted for the 10% rate, and dodged off on the 25% proposition. That was agreed to by a close vote of 79 to 75.

Notes from Eureka, Nevada.

[From our Own Correspondent.]

Signs of new life continue to crop out in our self-reliant camp, and local companies are organizing for the purpose of doing the work that in other places would not be done without the aid of foreign capital. Since the Ruby Hill Tunnel Company was organized others talk of similar enterprises, and I have no doubt that when the spring opens Eureka district will be the scene of much greater activity. Every day comes the intelligence of a "new strike." Nothing to cause great excitement, but something to encourage one and induce him to strive just a little harder. The time was when miners laughed at the idea of striking ore 1,000 feet beneath the surface, by driving a tunnel for that purpose, but since a fine ore channel has been discovered in the Eureka tunnel, and it has been shown that the body is richer, for its size, than any other yet found in Eureka district, there has been shown

A General Disposition to Prospect.

In that way. Other enterprises of the kind are about to be brought forward, and where the surface titles are without conflict, there appears no good reason why any tunnel scheme, now under way or even projected, should not pay back to the adventurer every dollar he may invest in any of them. The Eureka Tunnel ore body still holds out, and during the past three days nearly 50 tons have been extracted. The new hoisting engine will be in place and ready to run by about the 1st of March. The shaft will be sunk to a depth of 105 feet, and a drift run to connect it with the bottom of the winze from south drift. The shaft will then be carried down to a depth yet undetermined, and a new level started. The Ruby Hill tunnel, which enters Prospect mountain from the west side is looking well. A new contract was let to-day to run another 100 ft. What is wanted to facilitate the work is an Ingersoll "Eclipse" drill, which is just the thing for the place. The cost of operating one would not exceed much that of hand drilling, and the time saved would soon repay the extra cost. A little capital is needed. A company might be formed for the purpose of operating drills by compressed air, in this camp, that would undoubtedly derive large profits from their investments. There are many good properties in the camp.

Owned by Poor Men.

Who would give a large interest in their claims to ensure their rapid development, and they would offer good terms to such a company. Rapid development in Eureka district is a matter of much greater importance than a reduction in the price of labor.

On Ruby Hill there is very little change. On the main level of the Albion mine it is said that there is a very good prospect for striking ore. I believe that it is in a drift that has been run a great length on a fissure. Molybdates of lead and iron are coming in at the face, which are sure to lead to ore. I have not seen this, but it is important if true. There is nothing new at the Richmond or Eureka Con., unless it be a

New Kind of a Lamp

Now in use in the Lacon shaft. The water falls upon the light and does not extinguish it. It is a fine thing for a wet shaft, but I should say, rather dangerous for a dry one. It is known as the Vapor Oil Lamp, and manufactured by the Vapor Oil Stove Company, of Cleveland, Ohio. The first one brought here was recommended to Supt. Read, by Mr. Moore, of the Risdon Iron Works, where I understand they are extensively used. The advantage of this lamp, in wet places underground, is of so much importance, that I deem it my duty to call attention to it. At the Jackson mine there are many places where a great deal of prospecting has been done, and with poor results. Here tributaries have been at work for some time past, and are now ferreting out some good ore. These tributaries find ore in places where companies cannot work to advantage, and, as a class of miners, are very important. Many of them prefer tributating to day's pay, as they are not subjected to dictation from the bosses. They go to work and quit when they please, which suits them.

The Silver West mine, situated westerly from Adams Hill, has been leased to a party of miners for one year. This property, in the early days of the camp, paid well, as I understand, and I believe, from all the indications, that it will again come to the front.

Within the past week, about 100 tons of high grade ore has been sent to the Eureka Con. furnaces from the Home Ticket mine, the property of the Ruby Dunderbug Co., an English corporation. This ore is coming from close by the Clipper mine into which it will strike. On this account, several applications have been made to the owners of the Clipper for a tribute pitch, and arrangements will probably be entered into that will be of mutual benefit to the owners and the tributers. The Golden Rule tunnel will be turned in a direction to intersect this fissure. There are fine prospects now in the Unele San Con. mine. The north drift has cut through the quartz, and is now being driven on a seam of good looking iron.

The Magnet Series of patented locations have been bonded for sale. The property is a valuable one, and whoever buys it, will secure a prize well worth the having. Over \$12,000 bullion was shipped to San Francisco last week, by

Wells, Fargo & Co.'s Express, from the Bertrand mill. This was the half of a month's run. The leaching process is pronounced a success in this locality, and I hear other works will shortly be erected as the result. M. H. JOSEPH.
Eureka, Nev., Feb. 12, 1883.

Big Bend Tunnel.

By far the most important mining enterprise projected and under way in Butte county is the Big Bend tunnel, on the north fork of Feather river. Some three years since it was discovered that it was possible, by a tunnel 12,000 ft. long, to carry all the water of Feather river at its low water stage, and thus drain and render available for working 13 miles of river channel, what is known as Big Bend of Feather river. The magnitude of the work required a heavy outlay of capital, estimated at \$1,000,000, which has been secured from Eastern capitalists, and

far into the millions. Some time since when the project was first broached we gave a detailed description of the plan with a diagram showing course of tunnel, etc. At that time we gave an abstract of the report of the engineer who examined the location. Work is now progressing on the tunnel.

TOURISTS' ILLUSTRATED GUIDE.—We have received, with the compliments of the author, Major Ben C. Truman, the handsomely illustrated guide to the celebrated summer and winter resorts of California. The printing, lithographing, etc., were executed by H. S. Crocker & Co., and was the largest printing job ever handled in this city, the edition being 25,000 books of 240 odd pages. Of this edition, the Central and Southern Pacific railroad companies take 2,000 for free distribution—3,000 are to be sent to Australia, 1,000 to China, 2,000 to New York and 1,000 to Boston, and the balance are to be distributed to all first-class passengers passing

ARRANGEMENT OF TIMBERS IN STOPES.

the requisite surveys and examinations having been made, work was commenced on the lower or Dark Canyon end of the tunnel about the first of last December. The dimensions of the tunnel are to be, length 12,007 ft., width 15 ft., height 8 ft. It will be 1,400 ft. below the top of Big Bend mountain at one point. It will be run from the Dark Canyon face almost entirely, though it is intended, if found practicable, to work from the upper end also. A Barleigh drill carriage working four drills is used, and 45 men are employed in all capacities. The rock, so far as the work has progressed, is slate, requiring no timbering, and from surface indication it is expected that it will be the only rock encountered. It is estimated that about two years will be required to finish the tunnel and other necessary works to render the river bed available for working. N. A. Harris is the Superintendent in charge.

It is, of course, premature to speculate on the amount of gold in the river bed that will be taken out when the water is turned into the tunnel, but if the results obtained in working small portions by wing dams, etc., and the yield of the several bars are to be considered data to estimate from, it will be simply enormous and

Carlin and Merced, except 2,000 which are to be mailed to all the prominent hotels, libraries, clubs, and to noted Knights Templar, during the months of January and February. The other 5,000 have been purchased by Mr. E. S. Denison, who will dispose of them to the trade, so that retail book-sellers may sell them at the low rate of 50 cents each. Major Truman has made a very interesting and entertaining book, which does not read like the ordinary guide book. The descriptive matter is well written, and shows marks of careful and intelligent observations. A noticeable feature is the "Route of Travel and other Information," appended to each chapter, where is given just the very information the tourist looks for, as to hour of departure of stage or train, distance, time of arrival, hotels, accommodations, attractions, amusements and resources of the place, etc. All this is in condensed form. Even old Californians will be interested in this little work, as it describes all parts of the State. A valuable feature is that describing the mineral springs of California.

THE ALLISON RANCH MINE.—It is stated, upon very good authority, that the old Allison Ranch will be started up at an early date. That is the sort of news we like to hear. The Allison Ranch ought never to have been closed down, as any one acquainted with its history can testify. It is regarded now, by experienced men, as one of the best mining properties on the coast, and it is a matter of regret that it has been idle so long.—*Foothill Tidings.*

Mine Timbering.—No. 3.

The stoping is, as already observed, all carried on overhand; that is, a station or level is opened under the body of ore to be worked out and the progress of mining goes on from below upwards. In commencing the timbering of a stope, as, for instance, at a new station or level, commonly called the "track floor," the ground sills are usually laid parallel with, though sometimes at right angles to, the direction of the stope, or the walls enclosing the body of ore, and are frequently timbers of sufficient length to serve at the sills for several sets. The end of a ground sill is so framed, projecting a few inches beyond the last post, that the next adjoining sill timber, to be laid as the stope progresses, may be spliced to the one already in position, the joint being made under the post, as shown in the engraving given with No. 1 of this series.

The sills being laid and the cross-pieces adjusted in position, the posts are raised and the cap timbers are fixed in their places, everything being fitted carefully and closely together. No pins, bolts, or keys are employed in the framework. The walls of the chamber are sustained by a lagging of plank, inserted between the timber frame and the adjacent rock. This lagging consists of three-inch or four-inch plank, laid next the timbers and wedged, when necessary, by spiling. In time the lateral pressure of the ground holds everything firmly in place.

After a set of timbers has been introduced and finally put in place, a floor of three-inch planking is laid upon it to serve as a footing for the workmen in the space above. From this comes the local term of "floor" to designate any particular place or point in the mine; the stations or levels, about 100 ft. apart, being numbered from the surface down, first, second, third, etc., the floor being similarly numbered upwards, between the several stations or track-floors.

In working a stope thus, the whole width of the workable ground in the body of ore is taken down at once and the timbering supplied in its place, the advancing breast of the stope being carried forward from wall to wall; in bodies of ordinary width, this is from 10 to 20 or 25 ft., requiring, therefore, in cross-section from two to six sets of timber, like those just described.

In commencing a stope on the level of a new station, the ground set or first floor is put in, and as soon as sufficiently advanced in the direction of the stope the next set above is placed on the first of those below. Both then progress at about the same rate, the lower floor being kept sufficiently in advance of the upper to furnish platform and working room for the men above. As the work progresses, one set or floor is raised above the other until the station above is reached, each floor being kept a little in advance of the one next above, as indicated in the engraving shown last week, but better by the one on this page.

When it becomes necessary on account of the unsettled character of the ground, or for other reasons desirable, to extract the body of the ore as speedily as possible, it is not uncommon to commence, at the same time, a floor on the level of the station and another floor half way between the given station and the one above. For this purpose a winze is sunk from the upper station to the one below. From this winze the stopes are started, one on the lower station and one 50 ft. higher. The lower series of floors, usually six or seven in number, rising one above the other, arrive at length directly under the 50-foot sill, as the lower floor of the upper series is termed. By this time the mass of timbering is held in place by lateral pressure with sufficient security to allow of introducing without difficulty the timbers to be placed directly under the 50-foot floor. We gave in the engraving of last week an illustration of this proceeding. The main body of stopes, visible in the drawing, were started and carried on from the winze, that connects the upper with the lower level. The stoping on the extreme left, proceeded in a similar manner from another winze, further to the left, the stopes advancing to meet each other. After the available ground has been exhausted, the plank of the floors are removed for use elsewhere, and the vacant chamber filled with waste material. This is the custom on the Comstock and elsewhere on this coast. The expense is, of course, great, both for material and labor; but the work is thorough.

Gold-bearing Sulphurets preferred, having an assay value of \$20 per ton, or upwards. Address, A. B. WATT, P. O. Box, 2293, San Francisco.

AGAINST THUNDER POWDER.—The trial of the case of H. A. Haywood against the Thunder Powder Co. has been concluded before Superior Judge Lawler and a jury, resulting in a verdict in favor of plaintiff for \$7,500 damages. Haywood had the sight of his right eye destroyed, his left eye permanently injured, his left arm broken, 15 of his teeth knocked out and his upper jaw broken by the premature explosion of a charge of the defendants' powder which he was tamping near Salt Lake City on June 10, 1881. The plaintiff was a traveling agent for the defendant company, and was experimenting with the powder when it exploded. It appeared on the trial that the company represented to him that the powder would only explode from heat and concussion combined, and that it could be tamped with an iron rod with safety. The tamping was being done by plaintiff with iron. This is one of the instances where the people who made the powder did not use it themselves, and where the managers were reckless in their statements, not knowing really the exact nature of the compound they were using. The powder is no longer manufactured.

The following are some of the appropriations in the River and Harbor bill: Oakland, Cal., \$80,000; Yellowstone river, \$10,000; Red river of the North, \$10,000; Wilmington, Cal., \$30,000; entrance to Coos bay and harbor, Or., \$20,000; entrance to Yaquina bay, Or., \$30,000; mouth of Columbia river, Or., \$750,000. The last is the only appropriation for new work in the bill.

News in Brief.

THE sea swallowed up 1,790 vessels last year, involving a loss of 4,129 lives. Within the last five years 20,763 persons have perished at sea, not counting this year's disasters.

VICE-PRESIDENT HUNTINGTON, of the Central Pacific, said, recently, that there was no foundation for the talk of the union of the road with the Union Pacific.

COMMODORE T. S. PHELPS, Commandant at Mare Island Navy Yard, has received orders to be in readiness to take command of the South Atlantic squadron.

PETER COOPER was 93 years old Saturday. The event was quietly celebrated by a dinner, at his residence, on Lexington avenue, at which about 30 guests were present.

The outlook of crops generally throughout Great Britain is gloomy in the extreme. No part of the continent, east or west, has escaped rains and inundation. The immediate destruction of property has been widespread, but it is insignificant, as compared with the damaged prospects of the year.

The ordinance, prohibiting the maintenance of dangerous balconies, hanging gardens, etc., is being strictly enforced in Chinatown, where it has been violated the most openly.

The Editorial Excursion.

The Riverside Press and Horticulturist gives the following outline of proceedings of the approaching editorial excursion to the southern counties of California:

The arrangements are nearly completed for the editorial excursion to leave San Francisco on March 12, 1883, and proceed at once, without stop, to San Diego via Colton and the California Southern, arriving in San Diego on Tuesday evening, the 13th, putting up at the Horton House.

On Wednesday morning carriages will take the excursionists to the Cajon valley, thence through Spring valley to the Sweetwater, thence to National City, taking dinner at the National City Hotel, and spending the evening at the National Grange Citrus Fair, returning to the Horton House about 9 o'clock, where a reception will be tendered them by the citizens of San Diego.

On Thursday morning the excursion will return to Riverside to attend the Citrus Fair afternoon and evening.

On Friday a drive will be taken down Magnolia avenue and through the settlement. A reception will be tendered the visitors in the evening.

On Saturday the excursion will proceed to Ontario by rail via Colton to witness the laying of the corner stone of the Chaffey College of Agriculture, lunch being provided for them by the Chaffey Bros. A ride to San Antonio canyon and over the tract will be a portion of the programme.

On Saturday night the excursion will proceed to Los Angeles to remain over Sunday, when each member of the party will be at liberty to go where he pleases and return home at will, tickets being good until April 1st.

Circulars will be issued giving full details in a few days. Tickets will be sold, covering all traveling expenses, hotel bills, etc., for a little over \$30.

LADIES and sickly girls requiring a non-alcoholic, gentle stimulant, will find Brown's Iron Bitters beneficial.

A Cheerful Recommendation.

BENTON, CAL., February 4, 1883.
Messrs Dewey & Co., Patent Solicitors:—I am in receipt of my patent, "Improvements in Vehicle Brakes," obtained through your Agency, and would say I am much pleased with thorough and graphic description in specifications and drawings, and can cheerfully recommend you to anyone wishing to obtain favors in your line.—Truly yours, G. R. DEVAL.

At Reading, Pa., the sheet mill of the iron works has indefinitely suspended work, and 300 men are out of employment.

Oh, My Back!

That's a common expression and has a world of meaning. How much suffering is summed up in it.

The singular thing about it is, that pain in the back is occasioned by so many things. May be caused by kidney disease, liver complaint, consumption, cold, rheumatism, dyspepsia, overwork, nervous debility, &c.

Whatever the cause, don't neglect it. Something is wrong and needs prompt attention. No medicine has yet been discovered that will so quickly and surely cure such diseases as BROWN'S IRON BITTERS, and it does this by commencing at the foundation, and making the blood pure and rich.

Wm. P. Marshall, of Logansport, Indiana, writes: "My wife has for many years been troubled from pain in her back and general debility incident to her sex. She has taken one bottle of Brown's Iron Bitters, and I can truthfully say that she has been so much benefited that she pronounces it the only remedy of many medicines she has tried."

Leading physicians and clergymen use and recommend BROWN'S IRON BITTERS. It has cured others suffering as you are, and it will cure you.

Mining Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

DIVIDEND NOTICE.

MILL AND MINING MACHINERY.

F. A. HUNTINGTON,

No. 45 Fremont Street, - - San Francisco, Cal.

Oscillating Stamp Mill.

It has no Stems, Cams, or Tappets, and adjusts itself to the wear of the Shoes and Dies.
For simplicity, economy, durability and effective working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power. Awarded First Premium and Medal at Mechanics' Fair, S. F., 1880.

Manufactured by
F. A. HUNTINGTON, FRASER & CHALMERS,
45 Fremont St., S. F., Cal., 145 Fulton St., Chicago, Ill.
Improved Patent Grinding and Amalgamating Pans, Concentrators and Gold Amalgamators; also, Steam Engines and Mining Machinery of all kinds. Send for circulars.

F. A. HUNTINGTON,
45 Fremont Street, San Francisco, Cal.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care and attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.
The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in a very short time. One machine will concentrate the tailings from a five-stamp battery.

Send for Circulars.

SHINGLE MACHINE.

For simplicity, durability and rapidity of action, these Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

SAWMILL MACHINERY,
Of all descriptions made to order.

F. A. HUNTINGTON,
No. 45 Fremont Street, San Francisco

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS

All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

- NO. 1.—The most Powerful Explosive Compound now in use here.
- NO. 2.—Surpasses in strength any Powder of its class ever manufactured.
- NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much finer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The Giant Powder Company have also purchased from Mr. Nobel, the Inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same

NO. 7 IMPROVED AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

SEND FOR CIRCULAR.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

-OR-

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

Office, No. 230 California Street - - - San Francisco, Cal.

HYDRAULIC GRAVEL ELEVATORS,

For working flat gravel mines that have no dump.

Suices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY.

Auburn Quartz Mines.

Placer county quartz mines, for several years past shunned by mining capitalists, have, within the last six months, come out from under the cloud, and promise large returns during this year. In Auburn mining district are two classes of quartz veins, one in a slate country rock, the other in granite and porphyry. The veins in the slate have been found to contain occasional rich pockets, but no continuous ore bodies of any extent. The discovery of rich pockets at the surface led to the rapid opening and exploration of these mines, but the uncertainty and irregularity of the pay made mining at any great depth unprofitable. The quartz mines in the granite carrying the bulk of their gold contents in supposed rebellious sulphureted ores, and not readily obtainable by free milling process, were not worked to any extent or depth except in one exceptionable instance, and were considered, for the most part, of no economic value. Within the last two or three years they have been prospected and developed extensively, and to them the present, and probable future, prosperity of the quartz mining industry is due.

The Crater hill quartz mine, about one mile northwest of the town of Ophir, is the oldest, and thus far most extensively worked of these mines. The main shaft is down 800 ft. All ground east for 600 ft., and to a depth of 700 ft. is worked out.

In this part of the mine the first chute of ore was discovered. It was continuous, and in the several levels through which it was worked about 400 ft. long. It yielded in the aggregate about \$600,000. In sinking to the 800 foot level another ore body equally rich was encountered striking to the shaft from the west. This has been opened up during the last six months, and from every indication seems equal in extent and richness with the first-described chute. The mine is well equipped with steam hoisting works, and easy to work, the ground requiring little or no timbering, and the amount of water to be handled so small as to be controlled without difficulty. On the mine is a well constructed water-power 15-stamp mill. It will soon be started up, and will undoubtedly make a showing that will astonish mining men who believe this mine worked out years ago.

To the south and southwest of the Crater hill quartz mine distant a few hundred feet, are several promising mines. Most important of these, as the one on which most development

has been made, is the Gold Blossom. This mine was worked many years since and abandoned, the old mills not being able to work the ores which are heavily sulphureted. It was re-located three years since and several thousand dollars spent in prospecting and testing the rock. The results obtained being satisfactory, a sale was made by the local owners to some New York capitalists who have since sunk the main shaft to the 200 foot level, erected steam hoisting works, a 10-stamp mill with true and triumph concentrators, a large roasting furnace and made many other improvements. The mine has constantly improved as depth was attained, a much higher average grade of rock

ft. in depth, 500 ft. north of the first. Both of these shafts are in rich pay chimneys, and the ore taken out in sinking and drifting—very little ore being taken from the stopes has paid the cost of the shafts, a powerful steam hoisting gear on the first shaft, just put up, a ten-stamp mill and other improvements, and handsome dividends, in addition. The only capital invested by the owners was their labor, the mine having paid its own way from the start. The work already done has exposed a body of ore of great extent and high grade, the mill runs already made yielding from \$17 to \$50 per ton, and the mine will undoubtedly prove a bonanza to its owners.

North of the North Star is the Belmont quartz

Baker's Mining Horse-Power.

No mechanical appliance plays so important a part in the first stages of mine development as the horse-power, it being in the most cases the prospector's main dependence until sufficient depth is reached to justify a steam hoist. Those familiar with the requirements of the kind of work are well aware that all machines generally made for this use are very crude in construction as well as unsatisfactory in operation. The machine illustrated in the accompanying engraving is the invention of Mr. C. H. Baker, a practical mechanic and miner of long experience, who has for many years been

studying the wants of the mining interests in this direction, with the result of giving us a most convenient and efficient horse-power, especially adapted for miners' use.

The advantages claimed for this power are as follows: The machine is made entirely of iron, and is therefore very durable and will not be affected by exposure in dry or wet climates. The hoisting drum is completely under control of the man at the shaft, landing the bucket by operating the levers at hand, and by which means the drum can be thrown in and out of gear at will, or the bucket lowered by the brakes as safely and conveniently as by a steam power hoist. The brake and clutch

BAKER'S HORSE-POWER FOR MINERS' USE.

coming from the bottom of the shaft. Only the ore containing the least percentage of sulphurete, is run through the stamp mill, it being found advisable to dry-crush the heavy sulphureted rock and roast before attempting to amalgamate. The mill commenced running on the 1st of February and the first clean-up has been very satisfactory to the owners, so much so that an addition of 10 stamps to the mill immediately is projected by the owners.

Two miles to the northwest of the mines just referred to is another group on which considerable work has been done during the past year. They are all situated on the same lode, which has a general northerly course and is the largest in the district. The first claim commencing at the south end is the Morning Star. This was like all the other important mines in the district, opened and worked 10 or 15 years since, and abandoned as worked out when the pay chimney was lost.

It was relocated four years since, and has been worked continuously ever since on the average, five men being employed. One shaft has been sunk 260 ft., and levels run from 70 to 100 ft. long, 50 ft. apart, and another shaft 130

mine, purchased a few months since by several San Francisco capitalists, who have made extensive permanent improvements on the property. The mine is opened by a shaft down 210 ft. The stopes at present worked are on the 150 foot level, the vein there averaging four feet in thickness. The ore is similar to that of the two last described mines, except that it carries a small per cent. of blue carbonate of copper (azurite), which is not found in any other mine in the vicinity. The rock is free-milling, the contained gold being as a rule very fine. A 10-stamp mill was completed, and commenced running about the first of February. The result of the first six days' experimental run under very unfavorable circumstances, yielded an average of \$10 to the ton. A very unfortunate occurrence at this time has temporarily shut down the mine and mill, and through the publicity necessarily given it, the mining reputation of the district has suffered considerably. In this connection it is well to state that the mine has been examined within the last week by experts of high reputation, who pronounce statements as to the failure of the mine as absolutely false, and the charges made against the former ownership and management of the mine are in no way whatever warranted by the facts. The mine is conceded not to have been fairly tested yet.

The Star claims that Tucson will soon have the finest streets in the Southwest.

levers are provided with spring latch and quadrant giving the man in charge freedom of movement when the brake is operated, and locking the brake so firmly as to prevent the possibility of accident.

The drum will carry 500 ft. of five-eighths steel rope, and, running horizontally, will take up and pay out without friction. The drum working independently, a pulley may be connected to the end of the drum shaft, and connected by belt to a crank shaft on gallow's-frame, by which a pump may be run continuously, without interfering with the hoist, as the drum clutch can be thrown in and out of gear while running. This machine will hoist one-third faster, and carry a heavier load than similar powers, thus giving it much more capacity for handling both ore and water when required. It is a very light, compact machine. At the ordinary speed of a horse, a 1000-lb. bucket of ore or water can be raised at the rate of 120 ft. per minute. Two or more horses can be used if desired. No piece weighs more than 250 lbs., thus admitting of its being packed on mules to all inaccessible localities. The cost of erection is slight, as two men, in half a day, are able to put it in place, ready for work. While this power is designed more particularly for mining purposes, it is equally adapted to all other uses where animal power is required. They are manufactured by the Pacific Iron Works, of this city.

CORRESPONDENCE.

Tuscarora District

EDITORS PRESS:—The old camp of Tuscarora is again coming to the front, and will "boom" during the coming year if prospects are any indication. The Navajo shaft is crosscutting for the ledge at 450 feet. The upper levels are producing fine sulphuret ore, containing a good percentage of gold besides the silver. The shipments are regular, amounting to from \$17,000 to \$18,000 per week. The Independence, under the same management, is also producing well; the ore is of the same character as the Navajo and worked at the same mill. The two are shipping \$100,000 per month, which is a good showing for a 10-stamp mill. The old Grand Prize has good prospects. The Argenta has good prospects; is worked through Grand Prize shaft. Elko Con. joins the Navajo; has two inclines, the deepest of which is 125 feet, with drifts on the ledge all showing the permanency of the ledge, which varies from six inches to 2 ft. of pay ore carrying both gold and silver, the walls are good and give every indication of being a true fissure. The country rock is porphyry. The Elko Con. shows two distinct ledges, one of which has not been prospected to any extent yet. The company intend erect hoisting works in the spring and sink a new shaft which will cut the main ledge at the depth of about 200 ft. They are now extracting ore and piling it up on the dump. There are various other good prospects here, among which the Tuscarora Tunnel seems to have a good showing. Other mining propositions will be heard from here, as Col. Dow has promised the use of his pen in giving you the mining news and developments of this valuable mining region. As the disadvantages of a camp should be spoken of as well as the advantages, I will say the main drawback here seem to be the scarcity or entire lack of fuel. Sagebrush has been about the only fuel used heretofore, and an alarm has been felt that the supply on hand was not sufficient to furnish the town for the winter, but during the fine weather of November the teams were all engaged bringing in immense quantities of brush, and the mining companies are now getting stone coal from Elko, proposing to use that in future. It will certainly be cheaper and better, particularly in winter, when the snow covers the brush, making it a poor article of fuel for steam producing. Mr. Dove has a foundry here at which many of the new parts can be made, thus encouraging home industry.

The Centennial district, 20 miles from here, has very flattering prospects. One mine, the Gray Eagle, owned by Mr. L. I. Hogle, of this place, not long since shipped four tons of ore to Salt Lake as an experiment. Cost of shipping, including all expenses, amounted to \$54 per ton, worked \$210, thus leaving the very gratifying result of \$156 per ton net.

L. L. W.

Saving Fine Gold.

The Snake River Placers.

EDITORS PRESS:—You may think strange of receiving a communication from this far-off point, but you need not. We are a live people, who have fought, bled and died in the good cause, and I read your very excellent journal with much satisfaction, as I do our Eastern mining journals, the *Record and Engineering*. But I have to ask questions sometimes, and thus far have failed to get responses, the reason, I presume, being want of knowledge from the fountain head.

You have an article in your issue of January 27th, "The Black Sand Question—Reason for Loss of Gold." The writer speaks of the loss of gold occurring by reason of oxide of iron, coating, etc. This may all be so in that particular locality. Now, there is a field, very extensive, covering some hundreds of miles in extent, on Snake river, in Idaho, which has been known to be rich in gold (placer ground), fine sand and free gold. There has been much work done and little gold saved. The same thing has been held as to the gold in this region. The magnetic sand, it was claimed, held the gold as rusty gold. Much money has been spent experimenting as to the best way of saving the gold contained in these Snake river sands. But all have failed, thus far, in establishing the fact that there is any gold contained in the magnetic or iron sands. While there is good ground for the theory in the case of Mr. Paul, in Butte Co., Cal.—coarse sand and iron—there is ample room for this condition of affairs, and there is no doubt it exists as stated, and there is no doubt but he can save the gold where it exists in that condition.

Others have experimented on the Snake river sands, but can find no such appearance of gold, as (rusty or oxidized gold) claimed by some. Now, can you learn from your many correspondents in Idaho, to what extent they have and are working the Snake river placer mines. Over 2,000 persons are and have been working those mines from above American Falls to below Boise city. Some companies have claimed to have made very big money; others sank big

money. Of my own knowledge, the gold exists free but fine, very fine. Shuicing will save but a small proportion of it; hence, the failure of so many to get returns satisfactory to them for their investments. The Castle Creek Co. have paid dividends the past year regularly. Holyoke Co., on equally as good grounds, I am told, do not. "Why is this thus." Could you throw some light on this subject of the extent of the placer mining of Idaho, why many succeed, others fail? You will be imparting information sought after by many capitalists who are anxious to learn something new under the sun—to them at least. I claim no gold exists as rusty gold in the iron Sierras of Eureka now, and no time should be spent, or money either, in trying to find any there; this much I am satisfied fully of. Another thing I am fully satisfied of, there are inventors who have machines working on theory, who are willing and anxious to palm them off as grand successes in saving fine gold, even floured gold; yet they will not test their machines practically on Snake river sands—enough, they say, to show the machine will save fine gold on other properties similar. How similar? You know, I know, they know it is lack of confidence in their machines to do all claimed for them with these particular sands. Yet they will sell their machines, take the money and ask for a certificate framed by themselves of its superior qualities, etc.

Gold exists in paying quantities in the Snake river sands, providing 80% of it can be saved; and once this is demonstrated beyond a doubt, you may look for a stampede for Snake river equal to anything California ever saw. Town-plot speculators would be thicker than sand hill fleas, and twice as unwelcome. Idaho would step to the front at once. Mr. Paul is undoubtedly doing good work in the direction he is now working, mainly here, to mechanically and cheaply extract the sands. This applies to Snake river particularly; then how to save the gold is the next problem. I have no doubt as to the latter; it can be done cheaply and rapidly. Give some light on Idaho placer mines, their extent, work done, product from them, etc.

Respectfully,

F. W. NOBLE,

Detroit, Michigan, Feb. 6.

Copper Mines.

Short Discourse on Common Sense.

A correspondent residing in Candelaria writes to us to ask: "What security have we that if we go ahead and open the copper mines of this region any one will buy them of us, or that we will ever be able to make anything of them?" What security, we would ask our correspondent, has the ranchman who starts in to cultivate a piece of land that he will ever get anything out of it? What security has the man who sends his boy to the best school he can find that he will prove a blessing to him in his declining years? What security has the man who goes into stock business with two or three cows and half a dozen old ewes that he will ever rear calves and lambs? All these questions of "shall I do this," or "shall I do that," are to sensible men, at the present stage of the game of life in this world, exceedingly silly.

The main thing is for a man to go to work and do something in earnest, and there is no danger of his coming to want. The man who lies back and growlingly asks all his neighbors, "Do you think I should do this or do you think I should do that?" is in nine cases out of ten a man who is trying to find some plausible excuse for doing nothing at all. Yet we will answer our correspondent according to the best of our ability and without putting ourselves out very much for a man who, we think, is not likely to put himself out very much for any living soul on earth, even including himself and himself tolerably hungry. We will say that copper appears to be in demand, just the same as silver, gold, lead, saw logs, potatoes, cabbage and almost anything else that a man not too lazy to work has a mind to produce.

Thus: The Calumet and Hecla Consolidated Mining Company will pay their regular quarterly dividend of five dollars per share on the 15th of February, aggregating \$500,000. Total of dividends to that date \$22,850,000.

The Quincy Copper Mining Company have declared a quarterly dividend of six dollars per share, payable on the 15th instant, aggregating \$240,000. Total amount of dividends to date, \$3,470,000.

The San Francisco Copper Mining Company have declared their regular monthly dividend of five cents per share, aggregating \$2,500, payable on the 20th instant. Total of dividends, \$25,000.

Let a man go to work earnestly at almost anything, using proper judgment, and he will not starve.

Means of making money are not half so much wanted in this country as common sense and a will to work.

A man who goes into copper mining is expected to have a grain or two of sense; he is no more expected to spend his time at work upon rock that has not enough copper in it to pay for working than a man is to take his thousand or two head of cattle out into an alkali desert and expect them to not only pick up a living, but also to grow fat.—*Virginia Enterprise*

Mining Surveys, and Surveying Instruments.

Considerable difference of opinion exists as to the best mode of making underground surveys, as well as to the instrument which is the most reliable. Accuracy is the great object to be obtained, and the reliability of a survey made with the loose needle and the chain, especially when the rails are laid down in the workings of a mine, has led to a great deal of discussion. Hedley's dial is a favorite with many engineers, being both compact and easily used, whilst others look to what they consider the more correct theodolite. But even with the fast or loose needle liability to committing errors, or owing to a defective dial, errors, in fact, will be greatly reduced by repeating the measurement two or three times over. So far as regards the loose needle, the system carried out and inculcated by Mr. Henderson, of Truro, appears to be about the best. A true magnetic bearing is taken at some point, for which all the other angular bearings are afterwards reduced to their true magnetic bearings. In working it is considered best to have what is known as a left-hand compass. Attached to the north end of the needle is a vernier, properly balanced at the other end, so that each angular bearing could be read with precision. If the compass is fixed in a certain position, and the bearing read in a backward sight, that bearing is read from the needle, whether such is settled in its true magnetic meridian or deflected from such meridian by local or other attractions. However, whatever deflection there may be, it is equal in both the back and fore sights, so that the difference of the bearings must give the angular bearings of the two drafts. This mode is adopted specially for the magnetic needle, whether such is under the influence of attraction or not. In using the dial, if every sight was taken and put down exactly to a part of a degree or moved the sight, an error having any parts of degrees would be avoided. In taking a sight in any direction, and the light was moved until it was exactly part of a degree, all errors would be avoided. In the North at times surveys are made with the compass, and not by taking triangles with the chain; and to ensure accuracy an object was placed at each end of the base line of the survey, with the compass in the centre, and the bearing of that line taken. If the two objects could be seen through the sight in one line, then it was certain that the compass sights were parallel. Sometimes, however, it was found that both objects could not be seen in the same straight line, and then, of course, it was clear that the compass was uncovered, and ought to be reflected. From the bearing of the line they could draw on the plan another line, which would be the meridian line for that compass, and if that compass was 20 degrees wrong, or any number of degrees, if the survey was made with the same compass, the survey could be laid down as correctly as if the compass was the most accurate one in the world, because whatever angle was made to the base line, it was carried on to the plan by the same wrong compass.

We are told by one of the most scientific engineers that there were many instances on record where the compass had been used skillfully, and works carried out mathematically correct with it. On one occasion, he states, he was sinking a shaft, and had to do the work as quickly as possible, because one of the upcast shafts had fallen in, and he had to erect a furnace and sink a shaft at the same time. The survey was done with a compass, and when he went to examine the work there was not half an inch difference between the center of the shaft and the center line of the furnace drift. In connection with the taking of observations, it has been pointed out that the weather at times might make some difference. In taking observations at different times, the weather might have been different on each occasion, and might, and probably did, have a tendency to cause a variation of the needle from the true meridian. This difference between the observations made on one day and that on another might be caused by the atmosphere, for oxygen, which was a component part of it, was a substance which attracted the needle. In making surveys underground the rails had an effect on the needle, and it has also been found that bricks, most of which had a quantity of iron in them, would attract the needle. The importance of accurate surveys cannot be overestimated, and as there are various ways of making them the engineer in gaining experience should be able to test his work so as to ensure its accuracy, and at the same time should endeavor to obtain the best, and consequently the most reliable instruments. To those who prefer the dial, Hedley's improved, or what is, perhaps, better known as Davis' improved Hedley dial, perhaps, he found one of the best. The theodolite is a good instrument, and as reliable as most others, although, perhaps, not so readily moved about. Care, however, should be taken to obtain one with the latest improvements and of the best make. A greater degree of exactitude, one engineer states, is obtained in reading angles with the ordinary dial than can be obtained by using either the fast or loose needle—to repeat the reading of the angle several times consecutively, the same as is done in using the theodolite. That gentleman is in favor of a good dial, which appears to be extensively used, not only at home, but on the Continent as well.—*London Mining Journal*.

[From our issue of January 27th.]

Of Interest to Miners.

During the next few months we intend giving to the readers of the MINING AND SCIENTIFIC PRESS a series of valuable illustrated articles of special value. Among these may be mentioned a series of articles now in course of preparation on "Timbering in Mines," which will be very freely illustrated. This will give the methods in vogue on this coast, as well as those commonly practiced elsewhere. A series of articles is also being prepared on "Blasting in Mines," which will also be illustrated. This will be of great practical interest, containing, as it will, many details of every-day use to the miners. It will treat of the various methods of preparing blast holes, blasts, etc., the tools used, the explosive agents and kindred subjects.

In addition to these articles, which will be continued through several numbers of the Press, we are preparing a special mining map of British Columbia, with a description of the geology of the region and of the mining districts.

A map of the mining districts of Alaska will also be given, showing the location of the quartz mines now being worked. It will also show the course of the Yukon river, where the recent finds of placer mines were made, and where it is expected some rich developments will be made next season.

We have, too, in course of preparation a map of some of the Montana districts, and one also of the various mining districts of southwestern Nevada, along the line of the Carson and Colorado railroad.

It is intended to more fully illustrate the Press than heretofore, and with appropriate engravings. Such of the mechanical appliances of mining or metallurgy as may be practical in their nature we propose to illustrate and describe from time to time as occasion offers.

It is the aim of the publishers of this journal to keep pace with the progress of the mining industry. The mountains of the whole western side of the continent are now hunted over by the adventurous prospectors. New mines are being found every day, and new works are being put up. The MINING AND SCIENTIFIC PRESS has kept track of this business for 20 years, and been with it in its ups and downs. Its best efforts have always been with the prospector and working miner, and will continue to be so.

It has been our object to cull from every source such things as would be of practical value or interest to the class of readers with whom we are identified, and these efforts have been appreciated, we trust.

The Press has the satisfaction of knowing that its columns have never been lent to bolster up any scheme to fleece unwary stockholders, and that it has persistently upheld legitimate mining. Now that legitimate mining is in the ascendant, we feel that we have done our share in the good work.

We can of course do nothing without the co-operation of the mining community. While already possessing among our subscribers a large proportion of the progressive miners of the coast, there are new men in the business who may not be familiar with the merits of this journal. To these others familiar should present its advantages and call their attention to the desirability of becoming subscribers. It will be a mutual advantage. The more full our patronage the better paper we can make. We trust these words will not fall unheeded, but that they will result in material addition to our lists. We feel no hesitation in presenting our claims, feeling as we do that it is but justice to ourselves to call attention to them occasionally.

ELECTROLYTIC PROCESS.—We understand that W. Butler Johnstone has received highly satisfactory information from Germany, relative to the electrolytic process of refining copper, gold and silver, about to be adopted at the Mammoth Smelting and Refining Works. A gentleman writing to him from Ocken, Germany, where the process is in use, says: "I have for three and a half years made a long series of investigations on the electrolytic process of separating coppers, and have described the result of them in an essay. In answer to your questions, I have to say: (1.) There are five dynamo machines at work at Ocken, made by Siemens & Halske, 10-horse power each, and there they refine annually, between 10,000 and 12,000 cwt. of copper. (2.) The process is extremely successful, both scientifically and pecuniarily. (3d and 4th.) The electrolytic separation of copper, mixed with silver and gold, is by far the most rational of all known processes. (5.) The required number of workmen is very small. (6.) A machine of 10-horse power precipitates in 24 hours in 12 connected elements (or pairs of plates), 300 kilos of copper."—*Salt Lake Tribune*

EXPLODING AND BURNING.—Dust mixed with air is found, by many sad experiences, to be, under certain conditions, a dangerous explosive. Thus, if a large log of wood were ignited, it might be a week before it would be entirely consumed; split up into cord wood, and piled up loosely, it would, perhaps, burn in less than an hour; cut into shavings, and allow a strong wind to throw them into the open air—or in any way keep the chips comparatively well separated from each other—and the log would, perhaps, be consumed in two or three minutes, but if ground up into fine dust or powder, and thrown in such a manner that each particle is surrounded by air, it would burn in less than a second.

MECHANICAL PROGRESS.

Two Sources of Damage to Boilers.

The *Locomotive* contains the following hints which should be carefully read: Leakage at the girth, seams and around the tubes of externally-fired, horizontal tubular boilers is one of the defects most often found, and one which is sure to become very serious in a short time if not attended to, for it induces corrosion in one of its most dangerous forms. There is nowhere to be found a better illustration of the truth of the old saying: "A stitch in time saves nine," than in this matter; and also no better illustration of the economy and value of proper care and management for steam boilers. Leakage at the seams of boilers may be induced by a variety of causes, of which we need mention here only two—bad workmanship and bad management. When the defects are due to bad workmanship the only help for it is, generally, to dress and re-caulk the edges of the plates. Sometimes, though not often, it will be necessary to cut out the old rivets, insert new ones, and then dress and re-caulk. This is also generally necessary, when a boiler has been overheated through shortness of water or otherwise. Sometimes too much lap is given the plate, when it becomes impossible to properly caulk the seams.

The writer has in mind now a certain rotary blower, whereon the plates lapped four inches beyond the rivets. The result may be imagined. Obviously the only remedy in such a case is to reduce the lap. Leakage is often induced by feeding cold water into a boiler, and delivering it close to the hot plates over the fire. Severe local contraction is thus caused, which no material can resist, and leakage is sure to follow. The solid plates of the shell are very frequently fractured in this manner. Where the use of cold water is unavoidable the boiler should always be provided with a circulating feed pipe as a means of economy and safety.

In too many cases, however, the seams are shaken by the habit, which prevails extensively, of pulling the furnace doors wide open without closing the chimney damper. This is a very common way of checking the generation of steam, when there is a lull in the demand for it from any cause, and cannot be too strongly condemned. The effect of a large body of air some hundreds of degrees colder than the furnace and boiler, rushing along the under side of the shell, is sufficient to loosen the best joint that ever was made, and in many cases it has fractured the shell through the solid plate. The effect of this is even more marked with some types of internally-fired boilers, such as the "drop-line," for instance, than it is with the common return tubular boiler.

Another fruitful source of damage to boilers and one which has ruined thousands, is the practice of blowing a boiler off and immediately refilling it with cold water, while the brickwork is red hot. Nothing will tear a boiler to pieces quicker than this. Boilers have exploded with disastrous effect from this cause, hours after the fire had been drawn. Probably most persons not familiar with the matter, would be surprised to know the pertinacity with which cold water will cling to the lowest point of a boiler under these circumstances. Local contraction of such severity is thus induced that nothing can withstand its effects, and a few repetitions are generally sufficient to ruin any boiler.

Comparative Strength of Yellow and White Pine.

A comparison of the relative strength of the two varieties—yellow and Norway pine—was made at Dayton, O., with the following results: Specimens were dressed exactly an inch square, and these were broken in a testing machine, by placing them on bearings one foot apart, with the weight in the center. The southern pine had been air seasoned for two years and upwards, the Norway about one year to 15 months. The weakest southern broke at 736 lbs., the strongest at 1,102 lbs.; average of 8 specimens of southern pine, 904 lbs. The weakest Norway broke at 501 lbs., the strongest at 790 lbs.; average of 10 specimens of Norway, 702 lbs., showing the southern pine to be 28.7% stronger than the Norway, and that a southern pine sill of 4x8 inches dimensions is equivalent to a Norway sill of 5½x8 inches, with the further advantage in favor of the southern pine, that it can be got much freer of knots, and consequently stronger in comparison than these figures show, which are based on clear timber. Another test was made at a meeting of the Master Car Builders' Association, with the following results: Five pieces of each variety, one inch square, and 11 inches between bearing points, were experimented upon, the pressure being applied in the center. The outcome showed strength of yellow pine at 500, 510, 500, 490 and 530 lbs. breakage strain, or an average of 506, while Norway stood a strain of 620, 645, 730, 650 and 630 lbs., or an average of 635 lbs. These experiments do not appear to throw much light on the question of relative strength, and unless it can be attributed to the difference in seasoning, it is hard to find a satisfactory reason for such a discrepancy.—*Wood Worker.*

Effect of Heat Upon the Structure of Steel.

Mr. C. H. Reed, of Johnstown, Pa., writes to the *Iron Age*, as follows, in regard to the effect of heat upon the structure of steel: In the course of an extended series of experiments to determine how far the failure of steel (which was chemically satisfactory) could be attributed to injuries inflicted by its first cooling from a melting heat, I was led to make the following experiment, which shows graphically the enormous changes wrought in its physical structure by changes of temperature alone.

Crucible steel having the following chemical composition, C, .80, Si, .189; P, .081, Mn, .27, was cast into an ingot about 1 inch square and 18 inches long. The instant the pouring ceased the mold was knocked off, and the ingot, with its interior presumably still in a fluid condition, was plunged into cold water and allowed to remain until perfectly cold. Observe that the interior of the ingot was hotter than the outside, a condition that could never be repeated, had it been allowed to become cool and then been reheated. The result was a very curious structure, which under test proved to be very hard, but not strong, being loose, brittle and worthless generally.

A piece about a foot long was broken off, placed in a furnace, brought to a bright-red heat, kept so for about 30 hours, and then allowed to cool gradually. When broken it proved tough, strong and soft. About all the mischief done by the original cooling had been repaired, but still it did not show the most satisfactory condition of which the metal was capable, or such an appearance as it would assume after being hammered or rolled. One-half of the 12-inch piece was therefore replaced in the furnace, and subjected to another long and careful annealing, the result of which was no gain in strength, but it was fine in grain with a silvery appearance, and the fracture would readily pass for that of a bar of hammered steel of good quality.

In view of the above facts, and bearing in mind also that steel in cooling from its melting heat shrinks 15-16ths of an inch to the foot, it is not to be wondered at that serious mischief is done, and that strains leading to internal rupture of the metal occur through hasty and thoughtless handling of steel from its fluid to its first solid state. And it naturally follows that the risk of doing harm is proportionate to the height of the temperature and the rapidity with which it is caused to fall, and that molecular changes due to thermal influences seriously effect the quality of the metal, and are entitled to more attention than they usually receive.

A MACHINE for printing box sides and ends instead of stenciling, and doing the work 10 times faster than can be done by hand, has been patented by Connell & Dengler, of Rochester, N. Y. It has the advantage of printing, in a very rapid and clear manner, all cards or trade-marks much more perfectly than can be done by hand, thereby rendering it of great importance to the merchant or manufacturer. The type or form is cast in brass, and secured in such a manner that it can be easily and rapidly adjusted to print upon the board at the proper time. The inking rollers can be instantly raised from the type to prevent inking when the machine is not fed with boards. It will print boards varying from one-eighth to one and a half inches in thickness, and at the rate of 1,500 to 2,000 impressions per hour. The boards or sides of boxes are introduced to the machine in quantities of 10 to 20 pieces at a time, and the bottom piece of the pile is fed by a reciprocating bar to its proper place, in order to receive the impression at the proper time, the boards above dropping down to be fed in like manner until all are printed.

LIFE OF A LOCOMOTIVE BOILER.—A locomotive boiler, it is calculated, says an exchange, will last until the engine has traveled over 350,000 miles. On some lines, however, the boiler, under favorable circumstances, particularly when pure water is used, may travel 400,000 or 500,000 miles before becoming unserviceable. Assuming that the life of the engine is determined by the endurance of the boiler, and that if, under favorable circumstances, it will last the 500,000 miles, then during that time it is estimated that the fire-box will probably require to be renewed at least three times, the tires of the wheels five or six times, the crank axles three or four times, and the tubes from seven to ten times.

A MINIATURE LOCOMOTIVE.—An ingenious mechanic of Jamestown, N. Y., has completed a perfect locomotive, said to be the smallest in the world, being only 8½ inches long. The pumps throw a drop of water per stroke. The engine weighs 1½ pounds, and the tender 2 pounds and one-half ounce, 385 screws were required to put the parts together, and the mechanic was at work on it at intervals for eight years.

AN IRON WATCH.—An interesting feature at a recent county exhibition in Great Britain was an iron watch which had been turned out by Messrs. Crowther Bros. & Co., of Kidderminster, for the purpose of showing the extraordinary malleability of their metal. The watch is said to be perfect in every respect.

SCIENTIFIC PROGRESS.

The Microscope in Testing Timber.

A paper was recently read before the Franklin Institute, Philadelphia, on the use of the microscope in testing timber, and it was decided that if the microscope condenses the sample, further delay in testing is not worth the while. The larger the specimen requiring to be tested, the greater will be the gain the microscope will effect in avoiding the cost of further proof or the risk of using without such proof. Samples and micro-photographs were exhibited of bridge timbers which had proved faulty, but which a preliminary examination with the microscope would have promptly thrown out. The timber from which these poor specimens were taken was a fragment from a railway bridge wrecked in 1879. The timber was so excessively poor that, on mounting a specimen on the plate of the microscope, its weak and porous nature was at once apparent. The annular rings appeared about three times as far apart as they would be in good wood of similar kind. The medullary rays were few in number and short in length, while in good wood, on the contrary, they are of considerable length and so numerous that tangential sections present the appearance of a series of tubes seen endwise, or a number of parallel chains. After once seeing and comparing samples of good and bad wood, it is easy to recognize the difference with a pocket magnifying glass. The trunks and limbs of exogenous trees, as is well known, are built up of concentric rings or layers of woody fiber, which are held together by radial plates acting like treenails in a boat's side. The rings, representing successive year's growths, are composed of tubes, the interstices of which are filled with cellulose.

The slower the growth of the tree, the thinner these yearly rings, and the denser and harder the wood—other things being equal. Not only is the closeness of texture an indication of the hardness and strength of the timber, but the size, frequency, and distribution of the radial plates which bind the annular layers together may be taken as a very close illustration or sign of the character of the wood and its ability to resist strains, especially a breaking stress. The micro-photographs of good and bad timber show that in the strong kinds the concentric layers are close in texture and narrow in width, and the radial plates numerous, wide, long and stout, while in poor stuff the opposite characteristics prevail. The practical application consists in having such enlarged photographic sections, longitudinal and transverse, of standard pieces of timber, bearing a certain known maximum or minimum strain, and rejecting any piece which the assisted eye detects to have fewer rings per inch of tree diameter, fewer fibers, or fewer radial plates per square inch of section, or to use such pieces with a greater factor of safety. The advantage of the method is that it allows every stick in a bridge or structure to be tested before use.—*North-western Lumberman.*

Increase of Weight by Combustion.

Prof. A. W. Hoffman, of Berlin, has recently described to the German Chemical Society a number of new and interesting chemical experiments, especially instructive for the lecture table. One of the most interesting and easily performed of the series is, perhaps that of showing the increase of weight by combustion, an experiment which can be rendered visible to a large audience in several ways. One of his methods is to draw a small magnet through a mass of iron filings, and then suspend it, with its load, from one end of the balance. After a balance has been thus nicely adjusted, set the iron on fire, when the increase in weight by the accumulation of oxygen will be at once made evident. The one of magnesium instead of iron makes the experiment much more brilliant. The weight of magnesium need not exceed 0.5 of a gramme.

A still more instructive experiment consists in burning phosphorus in a closed quantity of air. The conditions are also more favorable, from the fact that phosphorus gains twice as much to a given weight as either iron or magnesium. The experiment should be made in a flask, in the bottom of which a small quantity of sand should be first placed, upon which the phosphorus (say half a gramme) should be then placed and ignited by dropping upon it a small piece of heated copper wire. Of course the wire should be first used in adjusting the balance. The flask should be closed with a cork, which must be removed to drop the wire. The combustion in the closed flask takes place slowly and quietly, with a slight increase of pressure at first. The sides of the vessel will be covered phosphoric anhydride. No change of weight will be noticed until after the bottle has become cooled, and the cork removed to permit of the readjustment of the air pressure. Several other interesting experiments in the same direction are described.

HIGHT OF LAND AND WATER.—If the continents and the bottom of the ocean were graded down to a uniform level, it is estimated by geologists that the whole world would be covered with water a mile deep, so much greater is the depression of the ocean bed than the elevation of the existing land.

Action of Poisons on the Petals of Flowers.

A. Anthony Nesbit, F. C. S., states in the *Journal of Science* that he has made some experiments on the action of various substances on the life of flowers, and for this purpose selected some of the best known alkaloids, viz.: strychnine, solanine, digitaline, quindine, atropine, quinine, cinchonine, picrotoxine, aconitine, brucine and morphine, using one-quarter per cent. and one per cent. solutions. The alkaloid of tobacco being very difficult to obtain pure, owing to its rapid oxidation, 5% and 20% solutions of tobacco (bird's eye) were used in its stead. The flower chosen for experiment was the narcissus, and the results showed that there was here a wide field for long and patient investigation.

Of all the 12 solutions, tobacco proved, in a very marked manner, to be most destructive to the life of the flower of the narcissus; the remaining 11 poisons, though but slowly injurious, nevertheless in some instances showed marked difference of effect, or, it may be said, symptom. Thus strychnine, next in poisonous power to tobacco, drew the petals upward, and made them dry and brittle, symptoms also exhibited by solanine poisoning, while quindine and several other alkaloids rendered the petals limp and rotten. Morphine, one of the least poisonous (to the narcissus) of the alkaloids experimented with, without destroying the flower, curiously enough imparted to the petals a flaccidity resembling that of the petals of the poppy.

CHROME YELLOW.—This process is based upon the solubility of metallic citrates in alkaline citrates, and particularly in ammonium citrate. This property applies not merely to the metallic citrates, but to a number of other salts. Thus, in presence of an alkaline citrate baryta is not precipitated by sulphates nor potassium ferrocyanide by the ferric salts. The insoluble chromates are all more or less dissolved by ammonium citrate, and in general more in heat than in the cold. Zinc, chromate, among others, which is little soluble when cold, dissolves with great readiness when heated. Lead chromate, on the other hand, is dissolved with much more difficulty. On submitting to the action of steam a color composed of lead citrate, ammonium citrate, and zinc chromate, a lead chromate yellow is obtained almost as solid as that produced by dyeing. By the action of steam the lead citrate and zinc chromate dissolve in the ammonium citrate, and give by double decomposition zinc citrate and lead chromate, which is fixed upon the fiber. The author exhibited a swatch which had been soaped at a boil for half an hour. It may be foreseen that solid greens may be obtained by adding to the color alizarin blue.—*M. Jaquet.*

TIDAL AND OTHER WAVES.—The phrase "tidal wave" has lately come into use to a large extent, but, unfortunately, it is usually misapplied. The "tidal wave" is the wave of high tide which sweeps regularly around the globe twice every 24 hours. It is a wave which obeys known laws, so that its continual arrival may be predicted with unerring certainty. But this phrase has come to be applied to movements in the air or water, or in human life which are exceptionally abnormal, and which cannot be predicted. A revolution in politics which no one anticipated is called the tidal wave. Such movements are waves, but storm waves, not tidal waves. But "tidal wave" has a suggestive sound, and so its misapplication will probably continue.

OPTICAL TELEGRAPHY.—It is proposed to place the Islands of Mauritius and the neighboring island of Bourbon, in communication with each other by means of an "optical telegraph." The stations will be about 134 miles apart, and will occupy an elevated spot on each island. From either station signals will be by the aid of a petroleum lamp, be flashed across the intervening stretch of the Indian ocean to the opposite station, where they will be received by a telescopic apparatus, which it is proposed to arrange so as to photograph the luminous flashes. If successful, this system of signaling is expected to prove of especial value in sending warnings of the approach of cyclones.

NEW RECEIVING TELEPHONE.—A new receiving device for telephones has recently been invented which may be applied to both ears at the same time—it being slightly adjustable to fit different sized heads. With this improvement the entire sound is utilized, so that a message that might be indistinct or faintly audible with the ordinary form of single tube receiver becomes clear and loud when received through this improved instrument. This invention has been patented by Mr. George F. Dailey, of 304 East Eighth Street, Leadville, Col.

THE FIRST COMET OF 1883.—Mr. W. L. Burton, second officer of the steamship City of Savannah, reports the discovery of a comet at 2 o'clock of the morning of January 12th. The ship was on the way from this city to Savannah, and about 25 miles southwest of Cape Lookout. The position of the comet is indefinitely described as "southeast of Orion." The supposed comet, faintly visible by the naked eye, was observed the same evening as early as 9 o'clock, the ship being in the river below Savannah.

MARIPOSA.
FROM MT. BULLION.—Cor. Mariposa *Gazette*:
see in a late issue, an interesting letter which is
principally devoted to the mines on Sherlock's Whit-
lock's and Saxton's creeks, written by an old pio-
neer. Dr. L. H. Bunnell, who inhabited that section
at an early period. These references by Dr. Bun-
nell remind me of other mines of no lesser im-
portance, some of which lie near my "cabin door"
in Princeton, and others of value on the estate known
as the Fremont Grant. These mines are known to
be valuable, and have in former years produced a
vast amount of gold, but it seemed under the late
management as if it used the most extraordinary ex-
tractions to spend the stockholders money, without
yielding adequate return in any shape or manner. The
mines of the estate would afford a remunerative re-
turn to the stockholders, or its owners, if only a
proper management could be had. The estate is
rich in minerals, and it is to be hoped that at no dis-
tant day a revival of the mining interest will take
place, and that the original mines will be reopened
and put upon a paying basis. There are numerous
quartz veins upon the estate yet unexplored, known
to be valuable. The Princeton mine is one with
which the writer is and has been familiar for the past
25 years, having assisted in building the first mill
ever put upon it. It was worked with great success
under the management of Trevor W. Park, who ex-

tracted therefrom hundreds of thousands of dollars in gold, which first gave him a stroke for further speculation, that with his management, accumulated to millions afterwards.

MONO.

STANDARD CON.—*Bodie Free Press*, Feb. 20. There were extracted and shipped to the mills during the past week 1289 tons of ore. The bullion shipment was valued at \$17,477.60. The main east crosscut, 1000 level, was driven 15 ft; total length, 124 ft, with no change. The east crosscut from the south drift is in 30 ft; progress 16 ft, through very favorable looking rock, with some quartz. South drift No. 2 has been extended during the past week 22 ft; total length 295 ft, showing a vein 4 ft wide. Upraise No. 4 from the drift has been extended 20 ft; total height, 55 ft. The vein is 7 ft wide. The slopes show no important change.

BOHLE TUNNEL.—The pulp assays averaged \$15.95 during the past week. There is no particular change to note in the appearance of the mine. About 40 tons of ore are being crushed daily. The bullion shipments continue about the same as heretofore reported.

GREAT SIERRA.—The main tunnel is being pushed forward as rapidly as steam and muscle can drive it. As soon as spring opens a large force of men will be set at work.

THAYER CON.—The west crosscut from the north drift, 700 level, has been advanced during the week 10 ft, and is now in 40 ft. The rock continues hard.

KENTUCK SWIFTEWATER.—This mine is looking unusually good. The mill is crushing rich ore, and the bullion shipments are large.

SYNDICATE.—Prospecting in this mine is still in progress. It is expected the mill will be started up in a short time.

BEHULL CON.—The west crosscut on the 570 level was run 25 ft during the week; total length 177 ft.

NEVADA.

FORD & McDONALD MINE.—*Grass Valley Union*, Feb. 15: The striking of an under ledge in the Ford & McDonald mine, a few days ago, may prove to be a discovery of some consequence. The ledge in that mine in which a number of rich strikes have been made is found at the depth of 120 ft from the surface and lays quite flat, and in places disturbed. It has been a theory with Arthur McDonald, one of the owners, that there was another ledge below this, and some time ago he concluded to sink below the present workings to determine this. He therefore started a prospect shaft in the drift 150 ft distant from the working shaft, expecting to strike the under ledge in 10 or 15 ft. He was disappointed in this, however, but having confidence in his theory he kept at work until he sunk to a depth of 45 ft, when he struck a strong vein, two feet thick, which shows well in sulphurets and prospects in gold. This ledge has regular walls, and has a dip to the south of about 40 degrees, and looks as if it is going to be a strong and permanent vein. Arrangements for pumping or drainage will have to be made before this ledge can be worked, when further developments will be awaited with considerable interest by the companies owning adjoining ground.

PLUMAS

GENESSEE MINE.—*Greenville Bulletin*, Feb. 14: Dr. Quinn is getting ready to start his mill again with the return of mild weather; the power being had from an overshot wheel, cold weather causes trouble by the accumulation of ice. The mill is now full and ore enough is lying back in the tunnel to supply the batteries for two months. In the various levels there is ore enough in sight to supply 60 stamps for a whole season. The lower tunnel is run into the south hill a distance of 400 ft and from this drifts are run in different directions on several ledges, of which the entire hill is full, the principal one being 25 ft wide and the greatest depth yet attained in the workings is only 12 ft below water level. A never failing stream of water flows down the canyon in which the mine is situated. If this property were in the hands of parties who would work it so as to fully develop it a very large and a valuable mine would be opened up. There is such an immense amount of ore, the water and timber are so abundant, that in all probability some parties who can work it properly will be by and get a hold of it. Thousands of tons of ore can easily be got that will pay about \$12 per ton.

GREEN LEDGE.—About two weeks ago a force of men was put to work in this mine, it having lain idle for a long time previously. The tunnel has been cleared up and pay ore is now being taken out; the best ore has a copper stain and contains a small amount of sulphurets. Such rock is difficult to mill, but works very well in an arrastra, and at present is worked in that manner. The average value of the ore as worked in this way has been thus far \$30 per ton. The bullion is very fine, being worth \$19.50 per ounce. The men are now at work in a rich pocket in a drift below the tunnel.

CRESCENT.—The water has all been pumped out to the bottom of the shaft and men started in there to clear up the drifts on Monday morning. The shaft was found to be in good order after all the years it had been standing full of water, and but very little repairs were needed to fit it for being used for work. Twelve stamps are now running and more ore is being got than this number can crush, but the scarcity of water will not admit of starting up more until after storm comes.

WATER.—The long expected storm came on Monday night; during the preceding day or two the wind set in strong from the south and it was evident that a heavy storm was brewing. Rain mixed with snow came down in a good steady pour that gives promise of long continuance; already the streams have risen considerably and from the mountain sides little streams that will soon be torrents are pouring into the reservoirs at Round valley. It is fair to presume that all danger of a water famine is now at an end.

NEW TUNNEL.—A new tunnel has been started on the west side of the hill from the Taylor-plumas mine and near the Stampfli ranch. The claim is owned and the tunnel run by Martin Fritsch, John P. Martin and Adam Hoffman. The entire ridge is believed to contain valuable quartz veins.

TUOLUMNE.

CONCENTRATORS.—*Tuolumne Independent*, Feb. 17: The Patterson M Co. have added sulphuret concentrators to their mill. These are built by Seebor, after pattern of the Schofield, and are thought to be

the best and most natural way of saving—being carried through long spouting boxes, with a slight grade—a stream of water frees them from the sand and they are thus made clean. Heretofore the sulphurets have been allowed to run off down the creek—but as depth in the mine is attained they become more abundant in the ore and of better quality which makes it a profitable object to save them.

It is contemplated putting an additional force of 25 men on the Riverside mine next month, or as soon as accommodations can be furnished in the way of a large boarding-house—the lumber for which, we learn, has been ordered. Work will begin on the building as soon as the material is received.

Nevada.

WASHOE DISTRICT.

POTOM.—*Virginia Enterprise*, Feb. 18: Since last weekly report the main south drift has been advanced 65 ft in the same course. There has been no change of any importance in the character of the ground passed through, nor any increase of water. The face of the drift is still dry. The machinery is all in good order.

SIERRA NEVADA.—The main north lateral drift on the 2900 level has been extended 25 ft. The joint Union Con. east crosscut on the 2900 level has been extended 26 ft, passing through stringers and bunches of quartz giving low assays. The face is now in porphyry.

OPHIR.—A joint Mexican fan station is being cut out at the 2900 level. Have completed the work of putting guides into the second compartment of the joint Mexican winze from the 2900 down to the 3100 level. On the 1000 level are repairing the drain tunnel leading out from the main incline to the Suro tunnel.

UNION CON.—The joint Sierra Nevada east crosscut on the 2900 level has been extended 26 ft, passing through stringers and bunches of quartz giving low assays. The face is now in porphyry. The joint Mexican east crosscut on the 2900 level has been advanced 20 ft.

MEXAN.—A fan station, joint with the Ophir, is being cut out on the 2900 level. Have completed the work of putting guides into the second compartment of the joint Ophir winze from the 2900 down to the 3100 level.

SURO TUNNEL.—The main force has been employed in the tunnel between points 4,000 and 7,000, making general repairs. Flow of water equal to 7,626,010 gallons per 24 hours.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*Candelaria True Figure*, Feb. 17: A crosscut has been started from the bottom of the main winze from the fifth shaft level. It runs toward the foot wall of the ledge found in the shaft, and has been extended 14 ft. The face of the crosscut has several spots of sulphurets, from which good assays are obtained. The slopes on the fifth shaft level are yielding a small quantity of high grade sulphurets. The ore body in the slope from the fourth shaft level has increased in width somewhat, and continues to produce the usual quality of ore. There is a material improvement above the first shaft level where the ore is entirely free from the slate, which has been troubling considerably during the past two weeks. But 55 tons of ore have been delivered to the mill daily during the week, owing to the cleaning out of the ore chutes preparatory to working a quantity of ore for Messrs. Farrington Brothers. The bullion shipments were \$15,208.78 for the week ending February 15th, and a total of \$32,416.15 has been made on February account to the same date.

MOUNT DIABLO.—The slope above the drift connecting winzes No. 1 and 2 shows a small amount of \$90 ore. A ledge of low grade ore, 4 ft wide has been developed in the slope from winze No. 2. This ledge carries about 18 inches of ore assaying \$70 per ton. The intermediate drift, west of winze No. 1, and below the third level, has encountered a 2-ft ledge of \$50 ore. Some \$90 ore is being extracted from an irregular ledge at a point near the head of winze No. 2, on the third level. The slope above the west drift on the third level, shows a foot of \$70 ore. The intermediate slope, above winze No. 4, is showing a small amount of ore assaying \$75 per ton. A small amount of \$200 chloride ore is being taken from the intermediate slope, above winze No. 1, and between the second and third levels. The slope above the west drift from the Callison winze shows some 18 inches of \$85 ore, that looks encouraging. Considerable \$75 ore is being stoped at various points in the intermediate drift below the first level, and the Tipton ledge continues to yield a small amount of \$80 ore.

COLUMBUS CON.—Connection between the first and second levels has been made by means of the raise from the second. This secures ample ventilation, and allows the work in that part of the mine to progress more rapidly. Several tons of good ore are being extracted from the slope west of the winze on the second level. The south crosscut from the west drift, on the same level, is in 17 ft, its face showing a favorable formation. No change has been developed in the raise from the west drift on the first level.

CRABB DISTRICT.

MILLING ORE.—*Esmeralda Herald*, Feb. 17: A correspondent writing from Crabb District says that owing to the late cold snap, there has been but little prospecting done in the district for some time. He denies the report that the bottom has dropped out of the Eagle Bird mine, and says that in the lowest workings of the mine there is good milling ore. The Messrs. Plummer have struck a good prospect about 6 miles north of Crabb.

ESMERALDA DISTRICT.

CLOSER DOWN.—*Esmeralda Herald*, Feb. 17: The Cortez mine was closed down last Wednesday evening and all of the miners discharged. There are a few tons of ore and tailings yet remaining at the mill which will be worked ere the stamps are hung up. After a two months trial it has been determined that the ore of the Cortez is so low grade that it cannot be worked even at a small profit. This event coupled with the present anxiety felt and existing over county seat affairs, has cast a gloom over the people of this place who were just beginning to dream of the long wished for boom.

INDIGNATION MEETING.—The Miners Union held an indignation meeting Friday. The Cortez Company proposed, through their Superintendent, to give the men due bills for the wages incurred in February. On inquiry due bills were not negotiable with any of the monied firms here, and in consequence the men

would not accept them. We understand that everything was finally settled amicably, the company paying the men at a discount.

EUREKA DISTRICT.

STRIKE IN EUREKA TUNNEL.—*Sentinel*, Feb. 18: A strike was made yesterday in what is known as the "Sullivan chamber" of the Eureka Tunnel, some 60 ft below the tunnel level. The face of the drift is all in ore, which extends below, above, and on both sides, for a distance of 6 ft in. It has not been explored sufficiently to determine what its extent will be, but the indications are favorable for its development into a considerable body. Two assays made from the new find go \$125 and \$150 per ton. The ore is of the character common in the mine, and has frequently been described. We learn from Gen. Connor that the mine is looking remarkably well generally, and that ore has been found in several other places, with favorable indications for prospecting. The flattering condition of the Eureka Tunnel, and its almost continuous improvement, are very pleasant to record, because it strengthens the assurance that this mine is one of splendid possibilities, while it strengthens the belief entertained by miners in the camp that Prospect Mountain is likely yet to compete with Ruby Hill in the production of the precious metals. Every improvement in the Eureka Tunnel is a substantial encouragement to all who own mines or are prospecting in that quarter.

FLOWERY DISTRICT.

THE MONTE CRISTO MINE.—*Virginia Enterprise*, Feb. 17: This well-known property will soon be producing bullion again and giving employment to many hands now idle. William Rodder, formerly pumpman at the Utah mine, has obtained a contract authorizing him to take ore from any point above the 600 level, he paying to the owners a royalty of so much a ton for the privilege.

MT. CORY DISTRICT.

LIVELY.—*Esmeralda Herald*, Feb. 17: A gentleman who visited this new mining district a few days ago informs us that things look lively and the prospect promising for a flourishing town of several hundred inhabitants within a few months. As soon as the road from Hawthorne is completed, lumber for buildings will be rushed in as fast as the teams at command can haul it. The mines are looking very well, and encouraging developments are being made. People from all parts of the State are coming in daily.

SILVER GLANCE DISTRICT

RED ROCK.—*Reno Gazette*, Feb. 14: Marshall Willard came in with some very rich rock from the Orpheus mine, which is located about five miles from the Ventura mine, in the direction of the Sweetwater mountains. Mr. Willard has a shaft down 130 ft, developing a 2-ft vein of quartz that yields from \$40 to \$50 per ton, though some has worked as high as \$130, with copper plates alone as the saving process. The country in that vicinity is full of mineral. Some of the richest float ever found in that very peculiar mineral belt has been picked up near the Orpheus. Mr. Willard has a five-stamp mill at work—a little prospecting apparatus that will crush only about a ton in 24 hours, but he is now making arrangements to put up a mill with a capacity of 7 or 8 tons a day. The Orpheus will probably be heard from as a bullion producer next summer. Unlike many other mining ventures, it has paid its way from the start, and there is money in the pot.

TUSCARORA DISTRICT.

BELLE ISLE.—*Times-Review*, Feb. 15: Drift north, 350-ft level, extended 25 ft. Formation more favorable for ore, and the vein shows an improvement. Work elsewhere in the mine progressing as usual.

ARGENTA.—The west drift from bottom to winze is in 52 ft, and a crosscut has been started for the foot-wall.

GRAND PRIZE.—The west winze below the 600-ft level is 31 ft deep. North crosscut on 700-ft level is in 125 feet, and south crosscut from face of the west drift is in 25 ft, in favorable looking ground. The flow of water is gradually decreasing.

ELKO CON.—During the past week the main drift of shaft No. 1 has been advanced a distance of 8 ft. The ledge continues in ore of a fair quality. Crosscut No. 1 has been advanced 6 ft through a formation composed of porphyry, spar and quartz. The spar and quartz are of a very encouraging nature.

NAVAJO.—The 300-ft level drift south, on the east lateral vein, has been extended 11 ft; total distance, 92 ft. Slopes on this vein and level show considerable improvement. Slopes on the different levels on the west vein are looking well at all points. Everything running smoothly at the mill. Average of ore milled during the past week, \$227.99 per ton.

Arizona.

WALKER DISTRICT.—*Prescott Courier*, Feb. 15: Walker mining district, 8 or 10 miles from Prescott, has now 200 men at work, opening mines, putting up houses and machinery, getting out timber, burning charcoal, etc. Our friend Waldemar is going over there to start and run a barber shop.

RICH STRIKE IN SOUTH PIONEER.—*Globe Chronicle*, Feb. 14: W. E. Spence, who returned from Pioneer Camp Thursday last, informs us that the last strike in the South Pioneer mine exceeds any of the previous discovered ore bodies in richness and size. The strike was made near the 300-ft level and is several feet in width, the ore being polybasite, carrying a large percentage of native silver.

In the Howard mine they are stopping at about the same depth that the new strike was made in the South Pioneer.

Work is being vigorously pushed forward in all the principal mines in the camp.

The new road from Casa Grande, on the S. P. R. R., to Globe, just finished, passes through the camp, the time from Casa Grande to Pioneer being only about 12 hours.

SMELTER.—The Long Island smelter shut down Tuesday morning for repairing and to await the arrival of coke en route from Wilcox. Work is being vigorously pushed at the mines with a view of getting a large reserve of ore ahead. There are 62,000 pounds of copper bars at the smelter awaiting shipment to the railroad by Stevens' teams, which are now discharging their cargo of 85,000 pounds of coke for the same company.

Supt. W. B. Devereaux, having thoroughly overhauled and refitted the old Carrie smelter, started it up last Thursday morning, on ore from the Tacoma Company's excellent mines. This makes the fourth large company whose smelters are in successful operation in our camp.

Colorado.

MENDOTA LODGE.—*Colorado Miner*, Feb. 10: Last week Wednesday Mr. R. O. Old shipped a carload of ore from this lodge to the Golden Smelting Works. The lot weighed a little over 10 tons, and returned 55 ounces in silver and 60% lead per ton. The gross value of the lot was nearly \$1,000. It came from level No. 1 east, on Beck and company's leased ground. The pay streak is solid and over 3 ft wide, of which about one-half, however, contains considerable zinc and is not shipped at present, but it will be. We understand that Messrs. Beck & Co. are about to double their present force of six men and put on a night shift. Mr. Old is preparing to start his long-meditated tunnel, which will cut the lodge 450 ft deep in a distance of 730 ft. Mr. Old shipped another carload of ore from the mine on Wednesday of this week, and expects to ship five cars during the present month. The grade of the ore has shown decided improvement for two months past.

Idaho.

BANNER ITEMS.—*Idaho World*, Feb. 10: The Elmhurst Silver Mining Company is working only three men this winter—running an upraise, which will connect the shaft that was sunk last fall, with the lower tunnel. This tunnel was run in 875 ft last fall and struck the ledge 80 ft below the shaft. Two veins were crossed, and instead of being a split in the ledge or two veins of the ledge, one on the hanging wall and the other on the foot wall as at first supposed, it is my opinion that they are separate veins. The tunnel was run on the first one, which dips toward the south, and the raise is running up on the inner one, which dips to the north. The raise is now up 50 ft and still the vein keeps its course. When the raise is up high enough a drift will be run south to strike the shaft. I have sent you some of the rock that was taken out of the ledge last week. It is about an average. The width of the ledge is from 6 to 18 inches. We had quite a cold snap here. Quicksilver lying on the mill floor froze so that it could be rolled about like balls of lead. We are now having some more weather like it. There is fully as much snow here now as last winter. It measures 8 ft. Several assays have been made of ore from there that went from \$200 to \$1,350 per ton. A district will undoubtedly be opened up there next spring that will astonish the natives.

Montana.

NOTES.—*Inter-Mountain*, Feb. 12: Energetic operations continue on the Clear Grit, and recent developments in the west drift have exposed an immense body of workable copper-silver ore. The ledge will soon be tapped in the 500 level of the Lexington.

The mammoth machinery of the Anaconda, which is the finest in the world, continues to run like clock-work.

The Granite Mountain mine at Philipsburg is producing handsomely and is said to be one of the richest silver mines in Montana.

It is reported that the Union Pacific Co., will soon reduce the tariff on milling salt to 15¢ per ton, which will still be \$7 more than that on coal. Fifteen dollars per ton, however, would suit the mill men.

New Mexico.

LAKE VALLEY NOTES.—*Herald*, Feb. 10: The Superior is working 20 men now, and the Bullion 11. The Germania mine, two and a half miles southeast of Kingston, is showing up a well defined vein, carrying galena ore.

G. W. Gregg reports the Cave Creek properties as showing well. The ore is in large bodies, in true fissures, and of high grade.

Mr. L. Stubenrauch, discovered this week the Bonito ledge between the Superior and Solitaire, and covering the same contract vein. He will commence work immediately.

The representative of the Studebaker Bros., South Bend, Ind., went up Sunday to examine the Solitaire, and probably to complete the negotiations in progress for the sale.

Mr. J. E. Roberts purchased this week two very promising properties near the head of the Animas river, about 12 miles from Kingston.

Mr. Webster, one of the pioneers of the Carpenter district, southeast of Kingston, came in Monday night for provisions, etc. He is working four mines, namely the Ohio, Carpenter, King and Queen. They are all fairly developed, and show heavy bodies of galena ore with some gray copper averaging 40 ounces silver per ton and 40 per cent lead. There are several other good mines in this district.

Utah.

TINTIC.—*Cor. Salt Lake Tribune*, Feb. 17: One of the most promising mining districts in Utah is that known as Tintic. The construction of the Salt Lake & Western R. R. from Lehi to the heart of the district has made it possible to work the mines and reduce the ores at a profit and conduct operations on an extensive scale. The owners of properties there are making preparations for turning out large quantities of metal, and the whole district will soon become one of the liveliest on the coast. The iron mines around Silver City are being worked at a profit to the owners, and bid fair to become one of the leading mining interests of the district. The prospects throughout the south end of the district, at and around Diamonds are being worked by the original locators, who for 10 years have remained by them, and their faith is not diminished as to the value of their claims. Throughout the camps there is a hopeful feeling, based upon the assurance of a prosperous year. The varieties of the ores in the district are greater than heretofore supposed, and, with the introduction of the new works in progress and contemplation, Tintic must assume a prominent position among the many precious metal-producing districts of the West.

PARK CITY.—There is no uneasiness felt here in regard to the failure of the Ontario Co. to pay the regular monthly dividends. Their object in discontinuing them has already been stated in the columns of the *Tribune*. We do not think this will have any bad effect on the camp, but, on the contrary, the increase of machinery and capacity will naturally create a demand for labor, which will in turn prove a benefit to our merchants. Regarding the Utah Eastern purchase by the Ontario Co., we believe that in this event a decided improvement would be made on the road, in the way of rolling stock, buildings and its capacity. The silver bars are shipped daily, as usual, notwithstanding the fall in the price of Ontario stock.

The Inyo Range.

Rich Mineral Deposits of a Remote Region.

The railroad which is being extended through outworn Nevada down into and through Inyo county will aid in developing a very great extent of mineral country. The Inyo range is particularly interesting in this respect as a large proportion is as yet but partially prospected. The volcanic origin of these mountains is evidenced by craters whose scarred rims are yet white with the ashes of dead fires. The Arnagosa, Argus and Telescope ranges are the most imposing of these mountains. The Inyos extend along the Owens Lake valley, from its eastern rim and the White mountains in Nevada southward, for a distance of 150 miles, parallel with the Sierra, from which they maintain an average distance of about 12 miles. They rise and fall in waving lines, gradually ascending until the loftiest summit is reached, opposite Mount Whitney, where they tower 10,000 ft. above the sea and over 4,000 ft. above the valley. A correspondent of the San Francisco *Chronicle*, not long since, wrote a very interesting letter describing the region under consideration, and from that letter we make some quotations:

Characteristics of the Range.

Though seeming to scorn connection with the Sierra, they have sent out to their base an offshoot of low hills called the "Alabamas," a line of skirmishers thrown across the river and set as a defense, challenging the encroachment of the Sierra upon the lowlands below—a curious group of hills rising like volcanic bubbles along the Sierra's sloping base. The rock formations of the Inyo range, having for their fundamental bed the eternal granite, are divided into slate, limestone and porphyry, stratas of which cut the surface in great parallels, or bold undisputed possession of vast districts. Its deposits run through all characters and grades, from the native metals to the purely chemical deposits. These are distributed with wonderful prodigality. Like all mining regions, the range has been divided into districts, which, though bounded by imaginary lines, have a character and nature peculiar to themselves. Following the range northward, these districts are divided as follows: Cerro Gordo, Russ, Beveridge, Union, Waucoba, Big Pine, Deep Springs, Bishop Creek, Piute, Sylvania, Montgomery and Indian Queen.

Cerro Gordo.

In Cerro Gordo, the southernmost district, lying abreast of the lake, vast dykes of limestone, slate and syenite cleave the rolling hills, into which the lower mountains unfold, alternating as they ascend toward the central mass, until the upper altitude is held by a vast limestone formation. In this, at the town of Cerro Gordo, 8,000 ft. above the sea, and 4,000 ft. above the lake, and lying at the base of the Cerro Gordo peak, was found the most extensive lead and silver deposits yet developed in the entire range, or in the State of California. From them have been extracted \$15,000,000. The extraction of ore from these deposits is at the present time suspended, though undoubtedly millions still remain to be uncovered, as the development of these deposits are of the most superficial character.

A Singular District.

The district lying to the north, and known as Beveridge, is one of the most remarkable mining regions in the world. It has features common to no other part of the range. The varicolored limestones which enter so largely into the structure of the range in Cerro Gordo, and which there tower in cliff, precipice and summit, are here beaten down from the occupation of upper slopes, and give place to granite. The limestones in this district form the flanks of the mountains, and do not, except in rare instances, rise in height above 4,000 ft, while the granite towers to over 10,000 ft, and forms the body and breadth of the higher altitudes and slopes. It does so, however, not without contest, for at several points are seen mighty peaks of lime that lift themselves toward the sun. The mineral of this district is gold. The lead, silver, copper and the various rare and peculiar metals found in other parts of the range are entirely absent in this granite formation, though they are met with in the bordering limestone. The ledges of quartz are exceedingly numerous, each ridge and canyon side being pierced by them.

If future operations shall trace these gold veins to the mountain's heart, giving them scope and permanency, this district will become one of the most wonderful gold-producing regions ever known. Although sufficient has been discovered to attract interest and attention, the roughness of the country has retarded development and prevented extensive operations. No part of the district is penetrated by wagon roads. Rocky trails alone, clinging in places to the face of tremendous cliffs, and overhanging giddy depths barely wide enough to receive the feet of the patient mule and burro, lead into this mountain fastness. As a result, but a single five-stamp mill has been erected in the entire district, and that with infinite toil was packed in sections by mules. This mill, though running for a part of the time only for the last two years, has produced several hundred thousand dollars, and this almost wholly from a single mine still in operation.

Other Districts.

The mining ventures at Chrysopolis, San Carlos and Mazourka canyon are historical, and woven into the early history of this section.

Northward the Inyos spread into a mass of milder forms, and open into a region less marked with the aspect of desert mountains. The savage ruggedness of Beveridge softens into broad and rolling uplands redeemed by forests of pine. Here, and reaching to the White mountains, are situated the remaining districts heretofore mentioned, where the base and precious ores are found in sufficient quantities to make these districts the arena of considerable mining enterprises. In Waucoba, the first district north of Beveridge, the high grade silver bearing lead ores predominate, and in instances give promise of permanency and richness. Streams of water, forests of pine, deposits of soda, salt, iron and lime are near at hand for the process of reduction, which will reduce the cost of mining to the lowest figures.

Saline Valley.

Standing upon the summit of the eastern slope and looking toward the east, but down, until the senses swim with the awful depth and distance, is seen Saline valley, stretching along the base of these mountains, a great basin, a desert valley, rimmed by volcanic hills, its wastes of billowy sand, its sloping dry wastes of rock and boulder, its shining patches of soda and salt blazing under the burning sky. It is a desolate, dreary region, its face of barrenness relieved only by the clusters of mesquit seen here and there. As viewed from these mountains it presents as clear a vision of desolation as could be well conceived. It covers nearly 200,000 acres of sterile land.

Valuable Deposits.

Thousands of acres of soda have been located, and in one place a mine of purest salt, covering over a thousand acres of unknown depth, has been located. As seen from the adjacent mountains, it shines in the sun with a fierce glare, and is clearly visible for over fifty miles. Enough salt is here already prepared for the markets of the world, and each year adds to the wonderful accumulation. The only question of its utility is one of cheap transportation. The soda fields here will also be of great value, as they can furnish fertilizing material to redeem a State from sterility.

INYO.

THE PREVENTION OF SMOKE.—In commenting on steam boiler furnaces the London *Engineer* says: "All our experience, extending over many years, goes to show that when the production of smoke is prevented by special devices for admitting air, either there is an increase in the consumption of fuel or a diminution in the production of steam. A noteworthy instance of this came under our notice recently. An extremely simple and elegant device for preventing smoke was submitted to an engineer. He was so much pleased that he had it fitted to the furnaces of a large Lancashire boiler, one of a pair, either of which could be used at will. An experiment was made by firing the boilers alternately week about, the same coal being used, and the same work being done by the engine, the same fireman being employed. The result was that smoke was practically entirely prevented; that there was no reduction in the steaming powers of the boiler; that the invention gave the firemen no trouble, and required no attention, and that the consumption of coal was increased by about 2 cwt. per day. The best smoke preventer yet devised is a good fireman; and providing the boiler is large enough for its work, the coal fairly good, and that the air is admitted—not too much—in a thin sheet, as by a Martin's fire-door, such a man will prevent the production of smoke and get admirable results."

ABOUT TO START UP.—The work of preparation about the mill at New Boston, which has been progressing for some days past, is nearly completed, and it is expected the stamps will begin to drop about the 20th instant. The ore to be crushed in this mill will come from the Lime Point and Lucky Baldwin mines, the former distant about two, and the latter 10 miles. Some 12 or 15 men will be employed in and about the mill, and once more will old New Boston be a busy place. It is a fact, one that is every day becoming more and more evident, that the little narrow gauge railroad has done, and is doing, more toward reviving old mining industries, and causing new ones to be started, in Esmeralda county, than would half a century spent in talk about big prospects, expecting thereby to induce the assistance of capital. When the matter of cheap transportation decides the subject, as it does everywhere in southern Esmeralda, then do men interested in mining conclude to commence operations.—*Candelaria True Fissure.*

THE OUTLOOK.—The number of new discoveries of exceedingly rich bodies of ore was never so great as during the year 1882. These valuable discoveries have not been confined to any particular State or Territory, but each and all of the mineral bearing portions of our country have furnished their quota of newly-discovered rich mineral deposits. During the year 1883 we may expect these rich discoveries to be increased two-fold over those of last year. The great increase in the facilities for reducing ore has created such healthy competition of affairs, that even ore that assays but \$5, \$10 and \$20 per ton can be worked at a profit. There is not a camp on this coast but has low-grade ore, and the time will come when it will all be worked.

The First Silver Mines on the Coast.

Some Interesting Scraps of Early History.

[Written for the Press by CHAS. SCHUCHARD.]

A few days ago I came across your publication of "Early History of the Comstock," Dec. 16, 1882. As the writer of that article seems to be anxious to establish true historical facts, I will make a few additional remarks.

It was in the spring of 1853 when Comstock presented to Maj. R. Allen, then Quartermaster General, in his office in San Francisco, a piece of black ore from Washoe. Allen showed the same to Mr. Killaly, a miner from Real del Monte, Mexico, and to me. Both of us pronounced it at once very rich sulphuret of silver, still an assay was insisted on. Killaly took the specimen to his office, and there we made the assay, which was between \$3,000 and \$4,000 per ton. Shortly after I learned that Killaly was dead. The excitement about this rich discovery had killed him. Maj. Allen proposed to me to go to Washoe to examine Comstock's discovery, but I declined, and returned to Arizona. If I do recollect right, you may find some notes on this in Blake's Mining Magazine, published at that time.

In regard to the first working of silver mines on the Pacific slope, after the country came in the possession of the United States, there is no doubt that it was in that part of Arizona south of the Gila river. In the year 1854 I came with Col. A. B. Gray on the preliminary survey of the S. P. R. R. across the country south of the Gila, at that time known as the Gadsden purchase or Mesilla valley. In the month of June we arrived in San Francisco. The interest in the Southern Pacific Railroad was then at high pitch. The information given by us did not fail to create some excitement, particularly our statement about the mineral wealth, although we could not offer substantial proof for this. A large collection of minerals gathered on the trip, including specimens of silver and copper ores, was buried by the boys in the Colorado desert, as useless stuff when the highly interesting pack-mule that carried the provisions and frying-pans declined to accompany us any further. Enterprising men like Major R. Allen, U. S. A., J. D. Wilson, Wm. Blanding, A. S. Wright and others concluded to send out an exploring party under direction of E. E. Dumbear. In October we completed our outfit in Los Angeles, and started, 20 men strong, toward Fort Yuma. I will give here the names of some of the Company: E. E. Dumbear, McElroy, F. Roustadt, P. Brady, G. Kibbers, George Williams, Joe Yancey, Dr. Webster, Porter, Alfonso Carson, Chas. Haywood, Bendal, M. Cook, myself, etc. Taking the road by Tinya alta, we discovered first the Ajo copper mine, about 90 miles E. S. E. of Yuma, where we left eight men to hold possession as best they could. Twelve of us continued to hunt for the Arizona mountains and the celebrated silver mine Plancha de la Plata, of which it is stated in Ward's Mexico, that a piece of native silver of 2,700 lbs. had been taken out by the Spaniards. After several months of search, we discovered this mine, finding first a piece of pure silver of about four ounces. A few days after a piece of 19 lbs was taken out of old shallow diggings, overgrown by stout oak-trees.

About this time our party at the copper mine was attacked early in the morning by a company of Mexican soldiers, headed by the Prefect and other authorities, who demanded the delivery of the mine, as situated in Mexican territory. (The boundary line had not been run then.) They threatened to take it by force if not surrendered inside of two hours. Mr. Haywood's spirited answer, "We don't think of surrendering; if you want to fight let us begin before the sun gets hot," settled that question. The troops retired to Presidio del Altar, Sonora, just in time to receive the news of our discovery of the long-lost Plancha de la Plata. Immediately our party was ordered to leave the country. Knowing our latitude, and being well aware that we had no right in Mexican territory, we thought prudent to comply.

From the Ajo copper mine the first lot of exceedingly rich ore was shipped to San Francisco in 1856, by the Arizona Exploring and Mining Company. The name of this company has been instrumental in conferring the name of "Arizona" to the Gadsden purchase. The Arizona mountains proper are situated in Sonora. In San Francisco I procured another outfit to work mines near Tucson. Worked first a copper mine about 35 miles west from there, and then a silver mine near San Xavier del Bac, for which a company was organized in 1856. The whole outfit for this, which after much delay arrived at Yuma, was afterwards lost with man and beast in the desert between Maricopa Wells and the copper mine. Only one man escaped. This crippled the enterprise so much that it came to a standstill.

About this time Mr. Herman Ehrenberg, who had been for some time on the Gila and in Sonora, had formed in New York the Sonora Exploring and Mining Co., of which Samuel Colt, of Hartford, Wm. Coleman, C. D. Poston, Maj. Hartley were Directors. This company arrived, with Mr. Poston, Ehrenberg and Brunton, M. E. in 1857 in Arizona and took up headquarters in the deserted town of Tubac. Shortly after, I joined this company. We dis-

covered, besides many silver mines in the Santa Rita mountains, those at Cerro, Colorado, and Arivac. There at the Heintzelman mine active mining operations were commenced at once, and very rich ore taken out. A lot of 22 tons, taken in 1858 to San Francisco, yielded at the works of Wass, Uzney & Warwick, \$450 per ton, other ore smelted at the mine \$900 per ton. We were then buying lead ores for flux from the then recently opened Patagonia mine, worked by old man Douglass and others. In 1858, Mr. Guido Kustel brought out a large lot of machinery for the Heintzelman mine for the reduction of silver ores by the barrel process. From that time the country became more and more settled.

Corralitos, Chihuahua, Mexico, Feb. 2d.

A Fine Mineral Region.

Speaking of the country rock in the vicinity of Owens valley, the Inyo Independent has the following to say in regard to several prominent districts: The formation of Russ, Beveridge and Ubehebe districts is principally granite and porphyry; that of Swansea, Cerro Gordo, Lee, Darwin and Lookout is mainly lime; that of Snow's Canyon, Sherman, Granite and Slate Range is porphyritic granite, the latter forming an unbroken mineral belt over 100 miles in length, and forming the western wall of Panamint valley. The formation of Panamint and Wild Rose districts is mostly lime; southward from Panamint it is granite, and that of Coso, Columbus and El Paso is granite and porphyry.

The Ores of these Districts

Are of many kinds and classes. Russ district has carbonate lead and silver and free gold ores; Beveridge, sulphuret gold and silver and free gold; Ubehebe, copper; Swansea, Lee, Cerro Gordo, Darwin and Lookout, carbonate chloride lead and silver; Snow's Canyon, sulphuret, free gold and silver; Sherman, Slate Range and Granite, sulphuret, chloride and base-milling silver; Panamint and Wild Rose, base-milling silver; Coso and Columbus, free gold and base silver; El Paso, copper, gold and silver. The ores of Beveridge, Russ, Snow's Canyon and Coso districts have usually been worked by free-milling process; Swansea, Darwin, Cerro Gordo and Lookout, smelting; Panamint, roasting and milling; Slate Range, milling. A mill is in process of construction at Reilly, Sherman district, to run as free milling.

The Mineral Belt

Extends nearly parallel to and at an average distance of about 50 miles east from the base of the Sierra Nevada mountains, starting at its southern end, at or near Calico, some 75 miles east of the Sierras, and running in a course west of north until opposite Independence, where it approaches within 20 miles of the Sierras; thence running almost due north a distance of 100 miles to the Indian Queen mine in Nevada. The mineral deposits along the base of the Sierras from Owens lake southward and the low volcanic range adjacent are so slight that they have claimed but little attention from the mining public, although a few mines of gold and silver have been discovered near Coyote Holes, in the vicinity of Walker's Pass, and northward in Alabama and Fish Springs districts.

CASE HARDENING LOW STEEL.—There are a number of processes for case hardening low steel or iron. It is desirable to have a carbon covering or envelope that does not evaporate or oxidize quickly at the temperature required for hardening. As the prussiate of potash contains in its anhydrous state only about 19% of carbon, while the potassium, iron and nitrogen are nearly 80%, it follows that it is too weak in carbon to be very effective in case hardening. As boiling water takes up nearly its own weight of prussiate of potash, a saturated solution may be made, to which is added as much bone charcoal, bone black, or charcoal from leather or horn as will take up the solution, or as much as can be made wet; the mass is then spread out and thoroughly dried in an oven. It will then be ready to mix with whatever may be used to make it adhere to the steel, such as oil, grease, or any other sticky substance. Bone, leather, or horn charcoal can be made by roasting it at a low red heat in a closed vessel, so close that no air can injure the product. A crucible or iron box covered with clean sand will do.—*Scientific American.*

BESSEMER STEEL FOR TOOLS.

—The application of Bessemer steel is constantly being extended. We have already shown that it is rapidly taking the place of puddled iron for nails, and, now, with regard to the possibility of welding or hardening this steel, it is claimed for the patent Siegfried process, now undergoing tests by the Central railroad of New Jersey and several furnaces in the Lehigh valleys, that turning tools, picks and bars, drills for rock work, and similar implements, may be made by this method direct from the Bessemer ingots rolled into bars. Satisfactory edge tools are also reported to have been made. The process adds about 25 cents per ton to the cost of the steel.

LEONARDO DA VINCI thus foreshadowed the telephone: "When one is upon a lake, if he puts the opening of a trumpet into the water and holds the point of the tube to his ear, he can perceive whether ships are moving at a remote distance; the same thing occurs if he thrust the tube into the ground, for then, also, he will hear what is going on far away."

Recent Contributions to the California State Mining Bureau.

USEFUL INFORMATION.

New Building and Cementing Material.

A German exchange describes under the head of "Tripolith," a material designed for building and cementing purposes, which has recently been patented by Herr B. Von Schenck, of Heidelberg. The extract given below is translated from the original article:

"The new material Tripolith, or triple stone, is a union of silicium, calcium and iron oxide. These elements are ground, burned, mixed, quickly cooled, then stirred with water and dried, the resulting product being an extremely fine gray mass. In its characteristics, Tripolith stands between gypsum and cement, possessing great hardness and power of resistance, which increase with the age of the material. The cohesive powers of the stone are not equalled by either gypsum or cement, and can be regulated in from 10 to 15 minutes, by the addition of lime water, in suitable amount. It can be poured in the soft state into any form, whether of metal, gypsum, lime or gelatine, and can be taken out of the form in 10 minutes, much more easily than can be done with gypsum. In all weathers it is the same, neither changing with heat or cold, or undergoing any chemical alteration when subjected to dampness or placed under water. Paint, applied to it, whether oil or lime, does not loosen or scale off, as is the case with gypsum." For use in various ways, Tripolith is prepared in the following mixtures:

1. One-half Tripolith and one-half fine sand.
2. One-third Tripolith with one-third lime, and one-third fine sand.
3. One-third Tripolith with two-thirds coarse, washed, river sand.
4. One-half Tripolith with one-half lime.

For purposes of safety, in resistance to water and fire, Nos. 1 and 3 are recommended. The experiments and trials with Tripolith have now extended over a space of two years, and the results have in all cases exceeded expectations. A particularly noteworthy instance of this fact is shown in the experiments made upon it by the royal commission for testing building materials at the technical school in Berlin, where its advantages were made so apparent, that it was recommended in place of gypsum or cement.

Not only is the Tripolith a satisfactory building material, but it is being largely employed in surgical practice, for bandaging, in place of the gypsum casts previously used. The eminent practitioners and authorities, Prof. Dr. B. Von Langenbeck and Prof. Dr. Czerny, give the Tripolith bandages their unreserved approval, on account of their quick, hardening lightness, and imperviousness to water.

"It is claimed that the new triple stone can be used wherever Portland cement has been commonly employed, with equal satisfaction, and at only half the cost."

THE WAX PLANT.—The wax plant, indigenous in Carolina and Pennsylvania, is now being cultivated on a large scale in Algeria, while its acclimatization in Tunis has been attempted with favorable results. The fruit, enclosed in a bag of coarse cloth, is plunged into boiling water, and in a few seconds the liquid wax floats on the surface. This is skimmed off and dried, and forms a good substitute for beeswax, as it has the same chemical composition. Its odor is agreeable, the root possesses medicinal virtues, and the leaves are used for protecting textile fabrics from the ravages of insects.

THE TELEPHONE.—It hardly seems possible that so recently as 1877 the telephone was a toy; yet such is the case. At the present time \$7,000,000 are embarked in the extension of the telephone in England, and this capital is already winning a revenue of \$500,000 a year. Until a very recent time the telephone business has been a monopoly in England, of which the postoffice held the controlling power, but this has been broken, and it is said that a very strong competition will very shortly be felt.

GLUEING.—French cabinet makers use a glue-pot with an inside pan made of glazed earthenware and divided radially into three divisions, in one of which is kept strong glue, in another weaker, and in the third water only, with a brush or piece of sponge for cleaning off superfluous glue from the work. Chalking the joints in glueing end-wood is not to be recommended; a better plan is to size the end-grain with thin glue first, and then make a smooth face before glueing permanently.

THE MANUFACTURE OF MILK SUGAR.—It is reported that the manufacture of milk sugar has been begun by newly invented processes at an Ohio cheese factory. Hitherto the \$100,000 worth of milk sugar used in this country in compounding medicines has been imported from Europe, mainly Switzerland, Germany, and France. It is to be hoped that the new industry will prove successful and applicable at least to all our large cheese factories. At present this element of milk is in large measure wasted.

BROZING LIQUID.—Ten parts of aniline red and five parts of aniline purple are dissolved in 100 parts of 95% alcohol, on the water-bath, and the solution, after the addition of five parts of benzoic acid, boiled (for 5-10 minutes) until it has changed its greenish color to light bronze-brown. Applied with a brush upon leather, metal or wood, the liquid produces a magnificent bronze coating.

BEATEN ALUMINIUM LEAF may now be obtained in books like silver leaf, and is largely used instead of silver for decorative purposes. Mr. Levison suggests heavy aluminium leaf as a substitute for tinfoil for coating Leyden jars, and similar electrical apparatus. Area for area, it does not cost much more, is much lighter, and permanently retains its polish. A book of 50 leaves of aluminium, of the ordinary thickness, cost 25 cents; of a thickness suitable for Leyden jars, 50 leaves about 4 inches square, cost \$1.00.

WOOLEN SHAWLS may be nicely washed if you put half an ox-gall into two gallons of tepid water. After washing thoroughly in this, rinse in another tub with the other half of the ox-gall and the same quantity of water; shake the shawl out and let it dry in a warm room, but not in the sun. Carpet-rugs may be cleansed in the same way, but, after washing, if they are scoured with a soft brush, they will look as bright as new.

TO RESTORE COLOR.—When the color on a fabric has been accidentally or otherwise destroyed by acid, ammonia is applied to neutralize the same, after which an application of chloroform will, in all cases, restore the original color. The application of ammonia is common, but that of chloroform is but little known.

WHERE A DOLLAR MAKES A MILLIONAIRE.—A Russian traveler in the Malay peninsula claims to have found in use there the smallest "coin" in the world. It is a minute wafer made from the juice of a tree. Its value is about the millionth part of a dollar.

A NEW PLANT, says an exchange, has been discovered in Mexico, which is remarkable for its fiber. It is thought that it will revolutionize textile industries, since it is even more beautiful than silk. It has not yet been named.

THE VERY LATEST.—At the last meeting of the stockholders of the Keeley Motor, they found a pressure of 27,000 horse power to the inch in the generator, and \$23.46 in the treasury.

THE SAW.—The buzz of the saw is heard in 25,708 mills in this fair land of ours, and \$146,155,385 worth of logs and mill supplies is used up every year, the product therefrom being valued at \$233,367,729.

rest are constantly at work destroying the germs of disease. But it is different with the water which we drink. It is quite possible for a well to become poisoned while yet the water is crystal-clear, and to neither taste nor smell convey any hint of its defilement. One dares not point the moral of an article like this with instances taken from his own neighborhood, lest the sensitive feelings of his friend be wounded. Therefore I will quote again from the *American Agriculturist*, in whose pages first appeared this startling account of a case of well poisoning:

In Bergen county, N. J., there is an ancient dwelling used as headquarters by American officers in the revolution, and ever since occupied by people of wealth, many of whom moved into the country for the health of their families. This house has a privy-vault located 60 or 80 ft. from the dwelling on lower ground. The well stands near the house and quite as far from the vault on ground higher still. The roots of an *Ailantus* tree somehow penetrated to the water and were supposed to cause a change in it. So the tree was cut down, the roots cleaned out of the well, and it was supposed to be purified. Some time after diphtheria appeared in the neighborhood, attacking only those whose systems were adapted to give it a lodgement through the subtle influences of foul air or foul water, decaying vegetation in the cellars, obstructed sink drains, putrefaction in privy vaults, or some such cause.

The family occupying the old mansion was visited. Nine out of 14 persons were attacked, and one died. Then, of course, everything was examined, cleansed and purified. The privy was found with some four or five feet of water in the vault, as it had been from time immemorial, except in very dry seasons. This was a bubbling seething mass when disturbed, odorous and vile. Half a barrel of strong solution of copperas was poured into it and a great change was at once perceived, but not here alone. The well water, which had been used both for drinking and washing, suddenly became very "hard," and upon examination was found to contain large quantities of copperas, proving absolutely that there was then, and doubtless had been for years, a direct communication from the privy vault to the well.

Is it likely, one may ask, is it even possible that this is a solitary instance? On how many California farms may not a similar state of things exist? We have all seen houses where the privy vault is by means 60 or 80 ft. distant from the well. What is going on under-ground, either by the burrowing of vermin, or the natural drainage during the rainy season, it is impossible to tell. One would think that the mere suggestion of such a danger would be enough to rouse the most indolent, and yet the article from which I have quoted ends sadly enough—"This terrible experience will be unheeded by the great proportion of the population. Other privies will contaminate the wells. 'Malaria,' as it is sagely called, will cause bilious fever, and chills, and typhoid fever, and diphtheria, perhaps, and the air will take the blame instead of the water."

Let us hope that among the readers of your paper there may be some wise enough to learn a lesson from the experience of others. A privy vault is always a plague spot, a shame and a misance.

There is not the slightest necessity for its existence upon any farm. Have it thoroughly emptied and cleaned, then fill up the hole with earth and stones, and substitute for it the earth closet of our later civilization.

This is so easily constructed that any man can make it, and so deliver himself and his family from one fruitful source of danger, of disease and death.

A CURE FOR SCIATICA.—A correspondent, writing to London *Family Pair*, says: "A cure for neuralgia and sciatica—and, as I am told, an unfailing one—is too valuable not to be recorded. An English officer, who served with distinction in the war with Napoleon, was once laid up in a small village in France with a severe attack of sciatica. It so happened that at that time a timman was being employed in the house where he lodged, and that this timman, having been himself a soldier, took an interest in the officer's case, and gave him the cure, which, in this instance, succeeded immediately and forever, and which I am about to set down. It is at any rate so simple as to be worth a trial. Take a moderate sized potato, rather large than small, and boil it in one quart of water. Foment the part affected with the water in which the potato has been boiled, as hot as it can be borne, at night before going to bed; then crush the potato and put it on the affected part as a poultice. Wear this all night, and in the morning heat the water, which should have been preserved over again, and again foment the part with it as hot as can be borne. This treatment must be persevered with for several days. It occasionally requires to be continued for as much as two or three weeks, but in the shorter or longer time it has never yet failed to be successful."

LACK OF SURGICAL SKILL AMONG THE CHINESE.—Lieut. Shore, in a lecture on China and Japan, says, that until the arrival of foreign surgeons, there was not a native in the whole Chinese Empire who could remove a tumor, treat an abscess, or even set a fractured limb with certainty, and even now there are no surgeons in the army or navy.

PINKEYE IN CHILDREN.—Several cases have recently been reported in at least two different places in California where a disease has been developed in children's eyes which closely resembles pinkeye in horses, and which thus far has baffled the skill of physicians. Chleo is one of these localities.

Passing Events.

This week we present our readers with a double sheet edition of the PRESS especially devoted to the interests of southwestern Nevada, and that portion of California bordering thereon.

The recent rains have been very encouraging to the miners in this State, and as we write (Thursday), there are indications of more to come.

The floods in the East and in Europe are reported as very disastrous, and stormy weather is reported from many quarters. Extreme cold seems the rule, also, though in this locality for a week or so we have had mild and fine weather, and have experienced no storm at all this winter.

By the end of next month the men who have been in the towns and camps all winter will begin to look about them and start at work prospecting. In the more northern regions, however, a month or more beyond that will have to be passed. Many men are anxiously awaiting the disappearance of the snow to begin their regular season's "prospect."

Southwestern Nevada—Early Explorations and Settlement.

Few sections of our mineral domain are attracting more attention just now than that occupying the southwestern angle of Nevada and the adjoining region over the line in California. Although this country was partially explored at an early day, a few adventurous prospectors having entered it soon after the discovery of the Comstock lode, very little was known about its mineral resources for some time thereafter; its remoteness, arid and sterile character and the unfriendly disposition of the Piute and the Shoshone tribes who inhabited it having prevented its more thorough examination. For 10 or 12 years after the first rush over the Sierra Nevada this outlying district remained a *terra incognita*, but sparsely settled and but little explored. Toward no other quarter did the mining frontier in Nevada advance so slowly as in this direction.

The Wily and Murderous Digger.

The native tribes dwelling in this part of the State, though a miserable and cowardly set, are treacherous and blood thirsty, having on many occasions killed or plundered such small parties of whites as through carelessness or the paucity of their numbers have invited attack. These savages earned for themselves a perfidious and murderous reputation at an early day, having waylaid and butchered the first company of whites that ever crossed their country.

More than 50 years ago a party of trappers under Captain Jedediah S. Smith, being in the service of the American Fur Company, were nearly all killed by these Indians while on their way from California to the company's camp of rendezvous on Green river; This occurred somewhere in the vicinity of the Montezuma mountains or possibly a little further west. Many of the prospectors who first entered this region were also killed by these miserable Diggers, the number who have so perished being larger than is generally supposed. These were the assailants of Breyfogle and his companies who while in search of the so-called "Lost Lode," were on two different occasions attacked and driven back by them, several of the party being killed and Breyfogle himself badly wounded. Though generally so unreliable and vicious these savages have sometimes allowed small parties and even single individuals to pass through their country unmolested. In the summer of 1860, Dr. DeGroot went far into the depths of this wilderness unarmed and alone, and although he traveled everywhere camping often near the wigwags of these people, they gave him no trouble, for the reason, probably, that there was so little in his outfit calculated to excite either their enmity or their cupidity.

From 1860 to 1863 it was considered unsafe for small parties of whites to venture further toward the southeast than the vicinity of Walker Lake, about 100 miles from Carson City. By 1872 the border had been advanced to the White Mountains, another hundred miles further on in that direction. Meantime, a good many miners who had gone out into these deserts to prospect for mineral deposits disappeared, and were heard of no more. Little inquiry was made about them at first, because no one knew whether they had been killed by the Indians or whether they had drifted off to some other part of the country, or, perhaps, used up and discouraged, returned to California. As late as 1867, it was deemed necessary to station a detachment of U. S. soldiers in Fish Lake valley, only 17 miles beyond the town of Columbus, to look after the Shoshones, who had committed numerous depredations in that vicinity. About the same time several settlers were killed, and much stock run off at Red Mountain and Palmetto, lying some distance north of Lake valley. A few years later some miners were killed in the White Mountains, to the south of Fish Lake valley, and all the whites forced to leave, this being the work of Joaquin Jim and his band. About the year 1873, the mining frontier was carried over the White Mountains to the basin of Death Valley and thence on to the Colorado; the Indians off that way having caused but little trouble thereafter. Meantime, the Owens river country had been pretty thoroughly prospected, and a number of mining camps established in it. Yet, here, too, the presence of U. S. troops was considered necessary—a strong garrison having been placed at Fort Independence, near Owens Lake, and kept there until the past few years.

Dry and Desert Land.

Besides the hostility of the aborigines, the extreme aridity and barrenness of this region have done much towards retarding its exploration and settlement. This is the most desolate portion of Nevada, "Death Valley" and the Amargosa, river of bitter waters, lying within its borders. Three-fourths of it consists of broad valleys or wide extended plains, waterless, treeless and nearly destitute of every form of vegetation. Scattered over these wastes are great fields of sand, alkali flats, salt beds and mud lakes, tracts covering thousands of acres being impregnated, in some spots very richly, with borax and soda. In the dry season, these salines glittering in the sun present a surface white as snow, many of them during the wet season being converted into shallow lakes. But little rain ever falls here, though immense quantities of water are sometimes precipitated in a few

minutes in the form of "cloud-bursts," and the snow falls to a considerable depth on the higher mountains. The whole country may be considered a high plateau, elevated from 2,000 to 5,000 ft., its highest portion being toward the north and west, whence it falls away to "Death Valley," on the southeast, which region is depressed below sea-level. Across this plateau run numerous ranges of mountains, the sites of the metalliferous deposits varied in kind and infinite in number. While this country affords a considerable amount of pasturage, containing also some few patches of natural meadow and arable land, its principal source of wealth consists of its mines, including the various salines above mentioned, some of which latter have already been partially utilized.

The Argonauts.

The wave of immigration that set in on the discovery of the Esmeralda mines, in 1861, carried into the western portions of this region a large population, which, with the receding of that wave a few years later was mostly borne away again, leaving the country almost barren of inhabitants. Some of these Esmeralda adventurers having, however, drifted as far east as Columbus, finding many promising mineral indications, formed a district, and, going to work, stopped there permanently; and thus was a beginning made toward settling the more westerly section of this wilderness, other mining districts having afterwards been laid out and gradually populated in the vicinity of Columbus. In 1864

Another Wave of Immigration.

Setting in carried a large number of miners into Nye county, far to the east. Being disappointed in their expectations there the most of these miners beat a speedy retreat, returning the same year whence they came. A few, however, remained, and, scattering to the south and east, explored the country off that way. These were the men who prospected the mountains on either side of the Sinkavata valley, a broad depression nearly 50 miles long, having the Shoshone range on the east and the Mammoth on the west. The Alexander mine, at Grantsville, is situated in the former and the Downeyville mines in the latter. These pioneer prospectors in the course of the next few years laid out many new mining districts extending from Barnes Park on the north to Death Valley on the south, a distance of nearly 200 miles. They were the organizers of the Barnes Park, Union, Mammoth, San Antonio, Indian Spring and the Lone Mountain districts.

The Owens River Country.

In 1862, some of the Esmeralda adventurers straggling south, prosecuted the search for gold and silver lodes, in the Inyo and Coso mountains, which border Owens valley on the east. Although this region lies outside the State of Nevada, it has a history very like, and actually forms a part of the desert lands we are considering. Here, too, the pioneers had many difficulties to contend with. The country was barren and a long way off. The Indians were troublesome and the ores rebellious. Water was scarce, and wood by no means plentiful, these, with a variety of minor hindrances, having formed such an aggregate of obstruction, as served to utterly defeat these first efforts at mining, and in the course of a few years nearly depopulate the country. After an interregnum of six or eight years, mining here was resumed, and prosecuted with varying fortunes, the success achieved at Cerro Gordo and a few other points having been more than offset by the failures that occurred at Panamint, Darwin and many other places. After a season of decadence running through a series of years, the mining industry throughout this region appears to be reviving. That it abounds with valuable deposits of gold, silver and lead, admits of no question, the disasters alluded to having been due mainly to the causes mentioned, but in part, also, to inexperience and mismanagement.

Another Tidal Wave of Immigration.

In the fall of 1868 the White Pine stampede having set in, carried during that and the following year a multitude of miners well on toward the southeastern border of Nevada. From White Pine as a center this army of prospectors spread out in every direction, those who penetrated the country to the south and west meeting there the van of the Esmeralda and the Nye Country Argonauts, who, during so many years had been slowly making their way toward the south and east, and thus, was a thorough exploration of this entire section of the State brought about and the subjugation of the Digger tribes finally effected.

ARIZONA.—Our correspondent and agent, Mr. B. W. Crowell, will soon visit the various mining camps and districts of Arizona in the interests of the MINING AND SCIENTIFIC PRESS. We shall be pleased to have our friends where he visits to assist him with such information as they are able to give him. In view of the fact that the PRESS has devoted a great deal of space to Arizona affairs and developments from time to time, and on special occasions, we hope to gain an increased subscription list there by Mr. Crowell's visit.

ONE week ago we noted the fact that the management of the Mammoth Mining Company would discharge men for patronizing saloons. We understand that about a dozen men employed at the smelters have been seen coming out of saloons, and the order was enforced against them at once.—*Salt Lake Tribune*.

The Mining and Scientific Press.

This edition of the MINING AND SCIENTIFIC PRESS consists of 24 pages, eight more than the usual issue, and is devoted mainly to the interests of southwestern Nevada. This region is a rapidly growing one and will be developed with more energy now that means of transportation are at hand.

We shall, as occasion offers, issue double editions of the PRESS and otherwise continue to improve it. That our efforts in this direction are appreciated we quote opinions from several sources.

Mr. Wm. H. Washburn, of Central City, Dakota, writes us: "Your paper is highly prized by me for the valuable information it in reference to mine appliances and operations; and I hope it will continue to improve as it has in the past years."

The Candelaria *True Fissure* says: "The Mining and Scientific Press now presents a very fine appearance, with its new dress and enlargement."

The following is from the Georgetown (El Dorado Co.) *Gazette*: "The MINING AND SCIENTIFIC PRESS has put on a bran new dress of type. It is growing more interesting all the time. So great has been the improvement in this journal of the miners that one who has not read the paper for some time would scarcely recognize the tried and true old friend of the miners' interests. Every enterprising miner should read the San Francisco MINING AND SCIENTIFIC PRESS, published by those sterling old-timers, Dewey & Co. If you cannot subscribe for it now, by all means send 10 cents for a sample copy. The practical hints and information which it curls weekly from the various mining localities of the Pacific slope, to say nothing of its valuable editorials and splendid illustrations, are calculated to be of invaluable aid to the prospectors, millmen and miners generally. One single idea obtained from the PRESS may prove the keynote to your success."

The Idaho *Messenger* (Challis, Idaho), in quoting some two columns of our annual review, says: "This excellent mining journal comes to us in all its beautiful new dress, filled with general matters, but pre-eminent in its mining news and cuts. It is the pride of the Pacific coast. * * * It gives a review of the past year, which is so much better than we could give that we quote."

Academy of Sciences.

On Monday evening, last, the California Academy of Sciences held its regular semi-monthly meeting, with Prof. George Davidson in the chair. The following resident members were then elected: Dr. F. V. Hopkins, M. D., Henry B. Osgood, Miss M. H. Jones, Mrs. Donald McLennan. Judge Richard Rising, of Nevada, and William S. Campbell were proposed for membership.

A joint committee, chosen from members of the Board of Trustees, Council and Academy at large, was appointed to consider the most expedient manner of obtaining a much needed permanent building for the use of the Academy, and the proper display of its museum to the public. It was composed as follows: James M. McDonald, Charles F. Crocker, Thomas P. Madden, Lewis Gerstle, George Davidson, Justin P. Moore, Chas. G. Yale, H. Herman Behr, H. W. Harkness, W. A. Aldrich, William Norris, Fred. Gntzkow, Jacob Z. Davis and Thomas Price.

Among donations to the museum were specimens of copper ore from Elko, presented by W. J. Hanks, Sheriff of Storey county, also gypsum in dolomite, and a large fossil tooth of the *Elephas Americannus*, found among dredgings taken from the bed of Coosaw river, South Carolina, by L. M. Keene, U. S. R. M. Prof. Joseph Le Conte read a paper "On the Genesis of Metalliferous Veins."

HAWTHORNE BOOMING.—Lots that could have been bought in Hawthorne a month ago for \$50 are now held at \$200. Seven or eight new houses are going up. Johnny Bennets, late of Bodie, is building a large house torn down at Silver City, and will be ready to open a first-class hotel in a few weeks. The Mount Cory road is nearly completed, and the talk about removing the county seat from Aurora to Hawthorne causes the little town to be looked upon with considerable respect. It will no doubt be a thriving camp this summer.—*Reno Gazette*.

In the Colorado Legislature a bill has been passed to tax the net proceeds of the mines. The capitalists who own the big mines are much exercised, and the bill is bitterly denounced. This vote of the Legislature shows that the miners no longer control legislation in Colorado.

The Carson and Colorado Railroad.

Its Strong Backing, Speedy Construction and Good Management.

This road commences at the Mound House on the Virginia and Truckee railroad, eight miles east of Carson City, Capitol of the State of Nevada, and extends thence in a generally south-east course to the town of Candelaria, a distance of 158 miles. It is a narrow gauge track and has been built and outfitted, within a little more than two years, having been commenced in the spring of 1880 and completed to its present temporary terminus in the summer of 1882. It is a very substantial and well appointed work, having been built with due regard to permanence and safety and equipped in a manner equal to any other road in the country. Being financially strong, this company have spared no expense necessary to insure for the road the greatest efficiency. The practical conduct of the work has from its inception been under the management of H. M. Yerington, a man of large experience in this line of business and for many years General Superintendent of the Virginia and Truckee railroad, which position he continues to hold. It has been largely due to his careful planning and mulling energy that the road has been built at a very moderate cost and in so short a time. Since the opening of the road it has done a good business, the company having pursued a liberal policy which has not failed to give satisfaction to the general public and meet with the approval of their patrons.

A Naturally Favorable Route.

The country traversed by this road, though dry and barren, was found to be exceedingly favorable for railroad construction the entire route, with the exception of one low range of mountains, being nearly level. There were no large streams or deep canyons to cross, making necessary extensive bridging, nor is there any trestle work along it. So, also, was there but little deep cutting or tunneling required here. There were scarcely any trees or boulders along the route to be removed, and no marshy ground whatever to be piled or filled in. As the track runs nearly all the way on the public domain, the right of way cost little or nothing. It may be said, in short, that this road was built at a maximum of speed and a minimum of cost, some delay having occurred after its commencement through non-arrival of iron rails and other materials.

A Region Rich in Mineral But Poor in Agricultural Resources.

While the country which this road crosses and is intended to accommodate is so generally arid and sterile, it abounds with valuable deposits of minerals of almost every kind, its principal resources in this direction consisting in its mines of gold, silver, lead and copper, concerning which a good deal has been said elsewhere in this issue of the Press. Until these resources are more fully developed the business of the road must, of course, remain comparatively limited. That the work of this development will now proceed rapidly, admits of no doubt, as it has already received a great impulse, having previously been kept back only through lack of the cheap transportation facilities, which the road will now afford. Hence forth great progress may be looked for in the various branches of mining throughout this whole region of country, which, as we have already shown is very extensive. Before the advent of the railroad only the richest ores could be worked here, or shipped from the country with any profit. Now, this is all changed, the rich mines paying largely, while many of the poorer ones, before idle, are being worked with satisfactory results. Many of the mines here carry a large percentage of lead, a metal that would not bear wagon transportation 200 miles over sandy roads through a desert country. Hence, this class of mines could not, before the railroad was built, be worked to advantage. To the Shawmut Company, which will hereafter be turning out large quantities of lead-silver bullion, there will be effected, through railroad carriage, a saving of many thousand dollars every month.

And thus will it come to pass, that while the railroad will stimulate mining, mining will make business for the railroad, this reciprocal action greatly benefiting both. The very barrenness of the country will work advantages to the railroad, as it will necessitate the importa-

tion of almost everything required in the mines. Provisions, fruits and vegetables, grain and horse-feed - even hay - lumber, and, after a time, fuel of every description, unless mineral coal shall happen to be found, will have to be brought in over the railroad, creating, with the ores and base bullion to be carried out, an immense freighting business both ways. With the railroad it has become possible for the inhabitants of the mines to enjoy many luxuries, such as fresh fruits and the like, which before they were deprived of. Express and mail time between San Francisco and Candelaria is now 29 hours - formerly 85 hours - while freight, if received in shipping order at all, was supposed to be on time whenever it arrived, provided it was not over three or four weeks on the way.

While the present traffic of this road is already so unexpectedly large, the future prospects of the company are of the most encouraging kind. That the enterprise is likely to turn out so well will be gratifying to many who have no direct interest in its success, since it required some nerve for a company to plunge into a vast

abundant crops of fruits, grass and grain. In the mountains, on either side of this valley, is a tier of mining districts, all of which abound with mineral wealth, and into which the railroad will infuse new life. After entering Owens river valley, this road will meet with but few obstructions, the country consisting of an open, almost level plain, clear on to the Colorado. It would be difficult, in fact, to find elsewhere 300 continuous miles more favorable for railroad construction than this. Across the Mohave desert, for a hundred miles, an engine might almost be run without rails, so level and hard, and so free from impediments is the gravelly surface. It is expected that a large population will next year gather into the region opened up by this railroad, as it presents one of the best fields on the coast for both prospectors, business men and investors.

Supt. H. M. Yerington has submitted the following annual report of the Carson and Colorado Railroad to the Secretary of State of Nevada: Amount of capital stock \$6,000,000; amount of capital paid up \$2,250,000. Owing

Determining Hardness of Minerals.

Hardness is a character of much importance in the discrimination of minerals. It is usually expressed by comparison with the following "scale of hardness":

- | | |
|---------------------------|---------------|
| 1. Talc. | 6. Orthoclase |
| 2. Gypsum (or rock salt). | 7. Quartz. |
| 3. Calcite. | 8. Topaz. |
| 4. Fluor. | 9. Corundum. |
| 5. Apatite. | 10. Diamond. |

The hardness of a mineral may be determined in different ways:

1. By attempting to scratch it with the minerals in the foregoing list successively.
2. By passing a finely cut file over the specimens, with a rather firm pressure, three or four times.
4. By attempting to scratch the specimens with a knife.

Several trials should be made to obtain certain results, and each method should be tried if possible. Thus, suppose the specimen is a piece of chalcocite, No. 2 (gypsum), fails to scratch it, but No. 3 (calcite), scratches its surface readily. Next, reversing the method, it is found that the specimens under trial will scratch No. 2 readily, but not No. 3. On trying it with the file it is not rubbed away so readily as No. 2, but more than No. 3. It would be sufficient to set down its hardness at 22.

Easy as this method may seem, some precautions are never-the-less necessary. Thus, in a fibrous specimen scratch directed across the fibres will always indicate a lower degree of hardness than the true one; the scratch should, therefore, be parallel to the fibres, or still better, to the surface of a transverse fracture.

A sound, undecomposed specimen should always be selected, since the hardness of minerals is greatly affected by decomposition. Many minerals are softer when first obtained than after they have been kept some time in a dry cabinet. In crystals the edges and angles are often considerably harder than the faces, and those of primitive form than of the modifications. The portion of the specimen selected for trial should be, as nearly as possible, of the same shape as it has of the comparative specimens.

Brittleness should not be mistaken for hardness. Many minerals which are too hard to be scratched are yet forced away in powder before the knife to some extent. Some minerals contain hard particles of foreign matter imbedded in them; these should not be overlooked.

A series of substitutes has been arranged for use when a scale of hardness is not available, i. e.:

1. May be readily impressed with the finger-nail.
2. Is scarcely impressed with the nail; does not scratch a plate of copper.
3. Scratches a piece of copper, but is also scratched by it.
4. Is not scratched by a piece of copper, but does not scratch glass.
5. Scratches glass slightly; is easily scratched with a knife.
6. Scratches glass easily; is scratched a little with a good knife.
7. Is not scratched with a knife, but yields to a file.
8. Cannot be filed, but scratches a rock crystal.
9. Scratches a topaz.
10. Scratches a ruby.

LUCKY PROSPECTORS.—A correspondent at Luning writes: The Calanity mine, distant some three miles northeasterly from here, was disposed of on the 13th instant, to a New York syndicate for a consideration of \$30,000. I. B. Giles, familiarly known as the "Deacon," and Arthur George are now the recipients of a modest fortune.

Map of the Carson and Colorado Railroad 1882.

Scale 60 Miles to One Inch.

desert like this, even though its mineral resources were known to be both varied and extensive.

To Be Pushed Ahead.

The objective point of this road is, as its name indicates, the Colorado river, to which it will, in good time, be extended. Already work upon it is in progress beyond Candelaria, its present terminus, the route having been surveyed and located for a long distance south of this point. The heavy work on the summit has been completed, except that on the tunnel, the only one there will be on the road, and this is almost finished. As the track is graded nearly to Benton, the cars will soon be running to that place, the center of a fine farming and grazing district. There is also in this vicinity around Partzwick and elsewhere a good mining region. But the mining, like the agricultural interest here, has suffered through lack of cheap transportation.

After reaching Benton the road will not pause, but be pushed on into the Owens river country, which it will probably reach sometime next year. Along Owens river, it will, for a hundred miles or more, traverse rich bottom lands, capable, with irrigation, of producing

to the road being in course of construction it is impossible to furnish information as to cost of construction. Amount of indebtedness: First mortgage bonds issued and due, \$2,370,000; sundry accounts, \$15,300.79; total, \$2,385,390.79; due this company from sundry sources, including stock, etc., \$45,432.88; amount paid for the transportation of freight, passengers, mail, express, etc. \$359,031.68, and received for transportation of construction from contractors, \$82,222.43; total, \$442,254.01; amount of freight of all kinds hauled, in tons, 56,581; amount paid for account for operating expenses, \$196,149.78; number of dividends paid, 2; amount of dividends paid, \$112,500; amount of interest paid on bonds, \$135,000—\$247,500; amount of net earnings, \$246,104.23. Engine houses and shops, 3; engines, 6; passenger coaches, 3; combination coaches, 3; box cars, 30; platform cars, 3; ore cars, 15; push and hand cars, 25.

To give an idea of the looseness of the ore in Tombstone district, and the little labor required to extract it, the *Epigraph* informed on good authority that not over 3,500 pounds of powder is used during a month. Some mines on the coast use more powder in one week than the largest Tombstone mines use in a month.

Mining Districts and Operations in Southwestern Nevada.

We publish in this issue of the PRESS a map of the country occupying the southwestern part of the State of Nevada, including a section of California lying adjacent. On this map are laid down all the important mining districts, towns and other places and objects of interest in this region of country, including the line of the Carson and Colorado railroad, so far as surveyed and determined. On this map only what may be considered the live mining districts are shown, being those in which a regular organization has been maintained, and in which more or less work is carried on; districts once organized but subsequently abandoned not being laid down. While the relative positions of the districts and the distances that separate them may not in all cases be absolutely correct, they will be found sufficiently accurate for most practical purposes. In the table given below the distances have been computed from Carson City, Bodie, Aurora and Columbus, all important business and mining centers.

Following the Railroad.

Starting from Carson City, the capital of Nevada, and following the Carson and Colorado railroad, penetrating the mining regions to the southeast, we arrive 20 miles out at the Pine Nut mountains, the first range that the road crosses. These mountains abound with gold, silver and copper-bearing lodes, some of which have been extensively developed and proven to contain large quantities of fair grade ores. On their easterly slope occur heavy veins of copper, some of which have been opened and worked with excellent results, a good deal of bluestone, for use in the Dayton reduction works having been made from the copper obtained here. With the cheapened transportation arising from railroad carriage, the richest portions of these ores will now be shipped to other market instead of being manufactured into bluestone, for which there are but poor facilities at the mines.

These mountains crossed, we arrived at Wabuska, 43 miles from Carson City, 35 from the Mound House western end of this road and junction with the Virginia and Truckee railroad. Wabuska is the shipping point for Mason valley on the West Fork of Walker river, and 13 miles distant to the southwest. This valley contains a large extent of good farming land on which fine crops of barley and alfalfa are raised with the aid of irrigation. Beyond this, the road passes for a number of miles through a country having hardly any agricultural resources other than grazing, the bunch grass growing sparsely everywhere affording considerable pasturage.

Arriving at the north end of Walker Lake we reach a point on the railroad nearest to

The Pine Grove, Lake and Cambridge Mining District.

Distant from 10 to 40 miles, Lake district lies on the easterly slope of the high mountains that border Walker lake in the west, Pine Grove and Cambridge being over the range, the former situate six miles west of the East Fork of Walker river and the latter on that stream but further to the south. These are all gold bearing districts

the ore being mostly free and of pretty good grade. In Pine Grove and Lake, wood is in tolerable supply, water scarce. In the Cambridge district these conditions are reversed. A ten stamp mill owned by Ex Governor Blaisdel has for some years past been making in this district a profitable production of gold, over 200 acres of land being also under cultivation here. At Pine Grove two of the several mills erected there have been kept running pretty steadily of late and the camp after a long season of depression seems to be undergoing some improvement. The railroad passes to the east of

Walker Lake.

A sheet of water about 31 miles long, from six to eight wide, and in some parts very deep. Walker river, in the summer when the snow on the mountains is melting, is a large stream. It discharges into this lake at its north end, keeping the water here nearly fresh, though further south it is so strongly impregnated with salt and alkali as to be unfit for use. Salmon trout are taken in considerable numbers at the north end of the lake. This is a palatable fish, and forms the staple food of the Indians, many of whom live on a reservation along Walker river, a few miles north of the lake. Three miles south of Walker lake is located

The Town of Hawthorn.

Shipping point on the railroad for Aurora, Bodie, Sweetwater, Bridgeport and other localities to the southwest, connection being also made here with the stages for all these places. A great deal of freight is handled here, a good wagon road having been built connecting the station with Aurora and Bodie. The project of building a railroad from Carson City to Bodie by a more direct route, once talked of, has, since the construction of the Carson and Colorado railroad, been abandoned. Situated in the mountains, 10 miles west of Hawthorn, is the Mount Cory mine, located on a lode reported to be over a hundred feet wide, and carrying much good ore. This we fully described in the PRESS of Oct. 23, 1882. Twenty-five miles further on, and bearing a little to the east of south, is

The Town of Luning.

Containing about 100 inhabitants, and like Hawthorn, built up since the advent of the railroad. Luning is already an active hamlet, and must become ultimately a place of large business, being the point whence a number of prosperous and very promising mining districts obtain their supplies, and from which they ship their ores and bullion. The mining districts tributary to Luning are the Santa Fe, Gillis Mountain, Paradise, Downeyville, Clarendon, Garfield, Silver Star, San Antonio and Excelsior. With the exception of Garfield, these districts were all organized from 10 to 15 years ago. For several years at first a good deal of work was done here, but owing to the expense of freighting in goods and the consequent cost of supplies and labor, operations were gradually suspended until the country became nearly depopulated. With the coming of the railroad, population is returning, and business everywhere beginning to pick up again. As much ore, both silver and copper, is shipped from Luning, the Melrose Smelting Co., of Oakland, have an agency here filled by Geo. W. Darwin, Jr., a capable assayer and a man otherwise well fitted for the business. In buying ores the following plan is observed: A valuation is placed on the ore delivered at the depot, the shipment made, and in a short time the coin is returned and paid over to the prospector, thus enabling him to develop his mine and at the same time receive the benefit of reduced rates of transportation.

The Santa Fe District.

Luning and Soda City seem to be the center of a broad mineral belt. Five miles from Luning to the east lies the Santa Fe district, where work is progressing in a number of good prospects, only one of which is in silver ore, the others being copper. The Lotta, a small vein, but very rich in silver and galena, is now being worked actively. Of the copper mines in the district, Copper King, Illinois, Sweet Vengeance, Calamity, Black Diamond, Wall Street and Stone Cabin are the principals. Among the first locations made here was the Copper King, on which the present owner proposes soon to erect two smelters of moderate capacity. The croppings on this lode are large, and it will undoubtedly prove to be an extensive mine when fully developed. It can be worked at a good profit with the present rates of transportation and fuel, and is rich enough to warrant the owner in so pushing work as to make it a paying proposition at an early day. The Illinois claim, in this district, has been prospected by two shafts, the one 10 and the other 40 ft. deep. The lode shows a width of 50 ft. on the croppings, though no crosscuttings have been made to show the width below. Ore assays from 16 to 60% copper; average, about 30% of the Sweet Vengeance, about the same may be said as of the Illinois. These deposits of copper ore and the so-called silver caves at Downeyville have brought a number of experts and other classes of mining men into the country, among whom I notice J. H. Crossman, J. W. Gashwiler, Mr. Bowie and S. E. Holcomb, of San Francisco, and J. W. Mills, Prof. J. H. McChesney, of New York.

The Downeyville Mines.

Considerable lots of bullion are arriving at Luning from the Downeyville silver mines, 35 miles to the east, where a new furnace, of 20 tons capacity, has been erected. This furnace started up Oct. 7th, and run until Oct. 14th, during which time it produced 40 tons of bullion,

worth \$305 per ton, in total value \$12,200, a very satisfactory result for a furnace of that capacity; 13 shipments, prior to erection of the furnace, amounted to 3,437 bars bullion; net receipts over all expenses of 13 shipments, \$35,085.97. It is estimated that there is ore enough in sight in the two caves in the Downeyville mine to keep the present smelter running three years, without further ore developments.

The Garfield District.

Situated six miles west of Luning contains a large number of promising lodes. The principle mine being worked here is the Farrington, which employs quite a large force of men. The ore, a chloride and bromide of silver, is sent to Belleville for reduction. Among other good looking claims here are the Lotta, Delaware, No. 1 and 2, Honest John, and Dolly Varden, on all of which work is being prosecuted.

Gillis District.

This district which adjoins Garfield on the north abounds also with good mineral indications, some of which are being actively developed. In the Gillis district six miles north of Luning are the Middlesex, Bay State, Yellow, and South Mountain mines, all being prospected and making a fair showing of silver ores. A custom mill here is much needed and would pay well.

Soda City

Twelve miles south of and next station to Luning, derives its name from the springs located here and of which there are two, only a short distance apart, the one hot and the other cold, chemical analysis shows the water of these springs to contain soda, magnesia, iron and borax in such quantities and proportions as render it valuable for medicinal purposes. As a good hotel has been erected and bathing facilities provided here, the place is likely to become a favorite resort for invalids, such as have already tried the efficacy of this water having been greatly benefited thereby. This hotel is owned and kept by Martin Brazanovich, who has already made it very popular with the searchers after health as well as with the traveling public. At this place the Esmeralda Copper Co. have put up a smelter of 30 tons capacity daily. They employ 23 men at the furnace and 30 at the mine; are working ore from Blue Light claim, which gives average assays of 17% copper; bullion product from five to five and one-half tons per day. They haul their ore 12 miles, and can work it at a profit, giving an assay of only 12%. They have a side track from the railroad to the smelter, by means of which coke is unloaded there, the bullion shipped on return cars. Supt. Center has charge of the works, and is making such success that copper production has become the absorbing theme here. It is a peculiarity of many of the metalliciferous veins in the districts around Luning and Soda City, that, although small, they carry rich ores from the surface, thereby enabling men of limited means to work them to advantage. The miner can get out small lots of this ore, take it to Luning and there sell it, getting his cash in a few days. In this way, he is able to open his claim, support himself, and often make some money besides without the aid of capitalists.

At Rhodes Marsh.

Five miles southeast of Soda City, and 142 miles from the Mound house, occur extensive deposits of the borates of lime and soda, common salt and other saline substances. A large building has been erected here, which answers the several purposes of railroad station, warehouse and refinery. The works are run by the Nevada Salt and Borax Company, who now employ 40 men, and expect soon to largely increase the number. They make one ton of refined borax, and ship large quantities of salt daily. In the manufacture of borax, they use 24 large tanks, of 3,000 gallons capacity each. These are made of galvanized iron. Sheets of the same material are hung in the tanks, which are filled with the concentrations or fluid extract of the borates. The latter are taken up dry from the marsh, placed in large receivers, and dissolved by the action of steam, then turned into the tanks through pipes.

The borax forms in crystals on the sides of the tank, and on the sheets of iron called 'hangers,' to the thickness of three-fourths of an inch. This process requires for its completion about six days. The fluid is then drawn off by means of a siphon, leaving the glittering crystals adhering to everything that was beneath the surface. To this marsh, which is six miles long and five wide, a railroad three miles long has lately been built, for the purpose of hauling the salts from the pits, which are excavated to the depth of three feet, or through the strata of salt. Under this the brine is found, and fills the pit to the depth of 8 or 10 inches. The brine evaporating, leaves the pure white salt, which is taken out and piled up on the sides of the pit, which immediately fills as before. This operation is repeated three times each year, many pits producing several tons each every season. Some of the salt thus obtained is dirty and unfit for domestic use. This is shipped to the quartz mills. The pure white is finely ground in a mill and put up in sacks ranging from 3 lbs. to 180 lbs. in weight. The present Superintendent, J. C. White, proposes to construct long pits, or canals, on each side of the railroad, thus saving labor in handling the salt, which can then be loaded from the pit to the ears. One thing remarkable is the fact that fresh water is obtained on the edge of the marsh in wells sunk below the level of the salt. In the southern, or dry part of the marsh, a spring boils up containing 5% borax.

At Belleville,

Next station on the railroad, is located the two mills of the Northern Belle Mining Co., of 20 stamps each; also large furnaces, the ore from this company's mines requiring to be roasted. The ore, of which about 65 tons are reduced daily, is brought to the mills from the mine, at Candelaria, eight miles to the southeast by rail. Belleville, the largest town in this section of the country, is a little dull at present, as but one of the company's mills is now running.

Candelaria.

This is the present terminus of the Carson and Colorado railroad being 158 miles from its initial point at the Mound house, eight miles north east of Carson City. Being in the vicinity of the principal mines in this region, Candelaria is an active place, and likely to grow with the further development of these mines, of which there are a great many in the mountain lying to the south of it. Although a great deal of prospecting has been done here in former years, there is not as much going on now as the promising appearance of these mines would seem to justify. The Northern Belle, located here, is undoubtedly a first-class mine with others seemingly as good in the vicinity. This town has heretofore labored under the disadvantages of scarcity of wood and water and of dear transportation, all of which are now in a measure removed, the railroad having cheapened the carriage of wood and freights, and works having been constructed for bringing in water through iron pipes laid down to the White mountains, 14 miles distant. These pipes which have been laid under ground to protect them against frost, traverse a very rough country, crossing at one point a depression 900 ft. deep. Seven miles southeast of Candelaria brings us to

Columbus,

For a long time the largest, as it was also the earliest settled town in this section of country. For the past few years its business has been on the decline, having been drawn away by Candelaria and Belleville. At one time there were several mills and roasting furnaces in operation here, but at present there are none. When the railroad comes to be advanced to this place, as it probably will be, business will revive, as there are many good mines about it, there being also an extensive salt bed in the vicinity, where any quantity of impure salt can be gathered by merely shoveling it up. The old town abides its time, its population and business dwindling away in the interim. Twenty-five miles to the southwest is situated

The Indian Queen Mine.

A dividend paying institution, with an excellent record, having paid its way from the first. The success achieved here has, however, been due as much to its superior management, under John Howell, general Superintendent, as to the merits of the mine itself. The ore, though rich, is debased as badly as ore can be; yet so thoroughly is it desulphurized and chloridized, by roasting in the Howell furnace, that 95% of the pulp assay is saved in working. This mine, which has been turning out bullion at the rate of about \$100,000 per year, has made a total production of nearly \$1,000,000, a fair proportion of which, has consisted of net profits. The property is well developed and unfitted, being opened up to a depth of over 400 ft., and supplied with a five-stamp mill and roasting furnace of the improved Howell patent. Large reserves have been established here, there being ore enough in sight to keep the mill running for a long time. Lying off to the southeast, are situated the extensive borate fields of Fish Lake valley, with the Silver Peak, Red Mountain, Deep Spring, Lyda Valley, Palmetto and Sylvania mining districts still further on in that direction. Many of the mines here have been well prospected, and are capable of making a large and profitable production of bullion, under a moderate expenditure of money.

The Montezuma District.

Lying 45 miles E. S. E. of Columbus, is one of the oldest and most important in this entire region of country. The first mineral discoveries were made here nearly 20 years ago, and so firmly were the original prospectors convinced of the value of the deposits that they remained in the country continuously, despite its remoteness, isolation and the hostility of the savages. The most of the locations made in this district belong to the Shawmut company, who own here a series of some 30 claims, all more or less prospected and nearly one-half of them developed with thoroughness and system. Ten or 12 of these properties may be considered first-class mines, large bodies of splendid ore having been opened up in each one of them. Great quantities of this ore have been raised and are now lying on the dumps at the mines awaiting facilities for its reduction. Some of this is milling ore, though the bulk of it requires to be treated by smelting as it carries from 20% to 30% lead with an average of about \$60 per ton in silver. Some 18 months ago the Shawmut Company put up a large smelting furnace at a point convenient to timber and also to their principal mines, there being, as was then supposed, enough water at this spot for all needed purposes. Shortly after they had completed their works, however, the water supply failed in a sudden and most unaccountable manner, compelling them to shift the site of their smelter down on the edge of the salt marsh five miles to the west, where they are about to rebuild it, and where they will have plenty of water, though they will have to haul their ores and charcoal somewhat further than before.

When this company shall have recommenced the work of reducing their ores, they will be able to make a large uninterrupted and profitable output of lead-silver bullion, their stock of ore being high grade, all sufficient in quantity, and the business under an exceptionally capable management. But for the above mishap which could not have been foreseen nor guarded against, the company would a year ago have been in the receipt of handsome dividends.

The Inyo County Mines,

Which cover a vast extent of country, have suffered still more by reason of their isolation and difficulty of approach than those of south-eastern Nevada. Consequently, they will receive corresponding benefits from the Carson and Colorado railroad, which is now being pushed rapidly towards them. If the road had only the mines in this region to depend upon, they alone wouldulti-

The Soda Industry.

The Reno Gazette gives the following description of the process by means of which the natural soda produced by the waters of the Ragtown lake, Nev., is prepared for market. The soda at Soda lake, three miles east of Ragtown, Churchill county, is very hard and crystallizes differently from most of the soda in Nevada. It is very pure, but the solar heat is not great enough to reduce it. Griswold & Epperson have found that by heating it to 500 degrees the quality is improved, but the quantity lessened by loss of water and excess of carbonic acid. They have just finished a reverberatory furnace with a hearth of iron plates, under which are two side flues and a center return flue to the stack. By this arrangement the heated products of combus-

Patterson District, Mono County.

The Sweetwater Mines.

Editors Press: - By request of your agent, L. L. Woodmansee, I send you a few items concerning the new and promising district of Patterson.

There is but one mill here, and that a five-stamp one, owned by the Summers Bros., and to which they are going to add another battery of five-stamp and pan room to accommodate their present engine being large enough to drive that amount of machinery.

Ore to supply the mill is packed on mules from the Kentuck (also the property of the Summers Bros.), a distance of about two and one-half miles down a steep trail. A wagon road could be built or a tramway that would

hundreds. Choice specimens from the Lady Hayes have assayed \$2,000. Quite a number of mines are bonded and some to large companies. If there are any sales and capital gets into the new camp we may look forward to the time when it will be the best camp on the coast.

Now, we will step back two miles farther into the mountains and on to what is called the head of Sweetwater canyon, there we find a group of mines extending over two miles in length with most flattering prospects.

I would like to take up each one of the mines that have the real merit according to actual showing and speak of their merits and demerits; but I have written several letters without getting information I desired, so I am not at this writing able to do anything like justice to the occasion.

The map which I send you is through the

mately afford it an ample support, as they are not only numerous, but capable of being rendered largely and profitably productive. The road, within the limits of this county, will traverse nearly a hundred miles of rich mineral territory, all of which must become tributary to it, as soon as completed, and which even now is affording it a large amount of business.

WORK FOR MINING RECORDERS.—The late amendment to the act creating Mining Recorders, says the *Tuscarora Times Review*, compels them to do more work, as it provides that it shall be the duty of every Mining Recorder of the State of Nevada, on or before the first Monday in January, April, July and October in each year to transcribe into a suitable book, and to deposit with the County Recorder a full, true and correct copy of the mining records of the respective mining district for the three months next preceding, duly certified under oath. The County Recorder shall record the same in the county records of his county, and shall receive the sum of one dollar for each and every notice,

tion are brought in contact with three times the length of the hearth, which is twenty-one feet, thus obtaining a great economy in fuel. Its capacity is three tons per charge, and it is expected that three hours will dry a charge. They have 400 tons on the shore of the lake and will be shipping to San Francisco as soon as the furnace dries. Captain Moger, of Reno, was the builder of the furnace, and it is unnecessary to say it is a fine job. It was built under the supervision of W. D. Linton, of Wadsworth, who made the plans. There are two lakes a quarter of a mile apart, but they are entirely different. The one where the furnace is located three-quarters of a mile across, and is estimated to contain 500,000 tons of soda. The other is about 700 feet across, and though it has been worked for 19 years there is no visible diminution of the mineral. It contains some very beautiful crystallizations.

BULLION shipment from Butte Montana, now average \$120,000 per week, and the copper matte shipment are maintained equally well,

expedite the transportation of the ore very much.

The Kentuck is prospected down to a depth of 400 ft. and the ledge there is splendid, showing it to be permanent. Then going north across the ridge and in the line of the Kentuck we find the home stake in the canyon about 1,600 ft. below, showing the same quality of ore; what can we say from this, but that the mines will be permanent to that depth, viz: 2,000 ft.

There are many other locations here as you will see by the map I send you, which is but a bird's eye of the country and showing its geological formation and the relative position of the different mines.

Now, we will step across another deep canyon to the south of the Kentuck and around the summit of Mt. Patterson. There we will find another group of locations, of which the M. & M., Viola, St. Louis, Alta, Lady Hayes and others are noted. Here we find good ore of high grade, some of which assays up into the

kindness of Mr. A. Soderling, who is a thorough assayer though is not very expert with drafting instruments; yet, the map is a very good bird's eye view of the topography of the district. The publication of the map will be of considerable interest to the mine owners and the public; and as I think the camp must come to the front sooner or latter, all that is done to attract the attention of the public and capital there is of mutual benefit.

I am sorry that I could not go into more detail. However, if there is anything I can offer in the way of answering any questions that I may be able to, it will be with pleasure.

G. S. HAWKINS.

Carson, Nevada.

The Montano copper produced by the Parrot smelter is sent direct to the manufactory of Thomas Wallace & Sons, where 11,000,000 pounds of the metal are annually consumed

Prehistoric Footprints.

The Remarkable Tracks Found in the Rocks of Carson Quarry.

Not long since some considerable excitement was created by the discovery of supposed human footprints of colossal size in the quarry yard of the State Prison at Carson, Nevada. There are unmistakable tracks of elephant, horse, bird and deer, and other tracks somewhat puzzling in their outline, but bearing a strong resemblance

cliffs, 10 to 30 ft. high, on which the nearly level strata are well exposed. (Figures 1, 2, 3, 4). In front is placed the prison building, forming the fourth side of the quadrangle, and the cleared space forms its yard. The stone thus removed has been used in the construction of the prison and other public buildings of Carson.

The strata exposed in this quarry, says Prof. Le Conte, consists of heavy-bedded grayish and creamy sandstones, separated by thin layers of shale. The sandstones, in many places, especially in the eastern cliff, are strongly affected with cross lamination, indicating deposit by rapid, shifting, overloaded currents—in other

of about 60 ft. This hill is formed of sandstone which had its origin in the detritus brought by wind and water from the Sierra. This point was chosen with a view to utilizing the labor of the convicts in quarrying stone for building purposes. As a result of this quarrying, the stone has been removed from an area of about one and three-quarters acres, and to a depth varying from 15 to 32 ft., showing the hill to be composed of layers of sandstone alternating with seams of clay.

"It was known that animal remains had been discovered in the above-named quarry, but no special attention seems to have been called to

time the shore of some lake, or perhaps pond, local and isolated, as its level was above that of Lake Lahontan. Presumably we stand on the shore of this ancient pond or lake, and as we look about us we see the footprints of a variety of animals, among which we recognize those of the mammoth, the deer, the wolf, of many birds, of a horse, and most important of all, the imprints of the sandaled foot of man. There are six series of the tracks of man, each being represented by a number of footprints (from 8 to 17), in regular order, and each showing more or less plainly the imprint of a sandal. Besides this, in one of the series the form of the

NO. 1.—MAMMOTH TRACKS.

blance, in many respects, to those which would be made by a gigantic man. The scientific world became greatly interested in these tracks, and several members of the California Academy of Science visited the quarry and inspected the tracks. Those who read papers on the subject at the Academy were, Dr. H. W. Harkness, C. D. Gibbs, R. E. C. Stearns, Prof. Joseph Le Conte and J. R. Scupham. Careful measurements were taken by Mr. Gibbs, and plaster casts were made by D. Harkness. We reproduce some of the drawings made by Mr. Gibbs which show the appearance and position of the curious tracks; and also give engravings

words, *river flood deposits*. We have, here, therefore, probably the mouth of an ancient stream. The stone has been removed down to an even shale stratum, or rather to two shale strata, about two feet apart, which form the floor of the prison yard. These shale strata are the track-layers. The upper track-layer forms the floor of the upper or eastern part of the yard; then there is a drop of about two feet to the lower track-layer, which forms the floor of the rest of the yard. The whole area thus cleared is literally covered with tracks of many species of birds and mammals. (Diagrams 1, 2 and 3). The area has been cleared, and the

fact until the appointment of the present Warden, Wm. Garrard, under whose quick intelligence, and by whose energy, a systematic effort has been made to collect and preserve these fossils. And not only this, he, together with Mr. Hanks, the Sheriff of Storey county, determined to have the situation carefully examined, and to this end they opened correspondence with the Curator of our Geological Museum, C. D. Gibbs. At one of the recent meetings of the Academy, Mr. Gibbs read the correspondence, which so impressed the members that it was determined at once to visit the locality. The formation, to which allusion has been made,

sandal differs markedly from the others. The first of these series which we examined is to be seen emerging, as it were, from the eastern side of the yard, where the cliff is 15 ft. in height above the tracks. This series consists of 12 tracks, to which number four were subsequently added by tunneling into the rock. These tracks were evidently made in a layer of sediment of perhaps two inches in depth, for below this layer we find the compact sandstone. In each instance the mud had been raised by the pressure of the foot into a ridge which entirely surrounded it. Each of the imprints furnishes us with evidence, as we believe, that the feet of

NO. 2.—FOOTPRINTS, SERIES NO. 1.

NO. 3.—SOUTHWEST CORNER PRISON YARD.

from photographs showing the general appearance and surroundings.

The Nevada State prison is situated on the plains of Carson, three or four miles from the Sierras. The main building has been placed at the base of a low rounded hill, sloping to the plain on all sides except to the south, where it abuts against a neighboring ridge of much older rocks. The hill consists of regular strata, nearly level to the eye, but really dipping 2° or 3° to the west, and it is evidently a remnant left by erosion, of a much more extensive deposit. It has been cut into on one side (the northern) down to the level of the plain, in such wise as to form a nearly level quadrangle about 100 yards square, surrounded on three sides by vertical

tracks exposed and trampled over by men and horses for 8 or 10 years, without attracting any special attention. Their importance was first recognized by the intelligent Warden, Major Garrard. To the stony hardness of the strata alone, do we owe the fact that they have been preserved at all.

We have not space to go into all the details which have been developed concerning these tracks, but will quote a few extracts from the papers read before the Academy. Dr. Harkness says:

The prison was built about 20 years since, on the extreme point of a hill having an elevation

is called by Clarence King in his geological survey of the fortieth parallel, the "Lower Quarternary." Referring to this region, he says it is composed of sandstones and clays worn down from the adjacent high mountains and deposited in the water and on the shores of a lake of many hundred miles in area, that at one time extended along the eastern base of the Sierras and to Central Nevada, and having an elevation of 4,388 ft. above the sea level. Pyramid, Winnemucca and Walker lakes, and the sinks of the Carson and Humboldt are now the lower points of this prehistoric lake, which spread its waters in the pliocene age, and which Mr. King has called Lake Lahontan.

"It also gives evidence of having been at one

the one making the tracks were protected by sandals. In no single impression do we find conclusive evidence of this fact, but when we study them as a whole we find that which is wanting in one is furnished by others which follow."

"In nearly all, the toe portion is well shown, it being as smooth as the work of a mason, for the distance of two or three inches. Backward from the toe we generally find the imprint of the outer portion of the bottom of it. When studied as a whole we can determine with a good deal of exactness the actual length and breadth of the sandal, which we find to be 18½ inches in length, eight inches at the ball of the foot, while the heel is six inches in breadth. In its outline the impression follows clearly th

NO. 4.—BLUFF AT GUARDHOUSE NO. 5, SOUTH WALL.

shape of the human foot. From the great toe outward there is a really graceful curve, which draws in towards the heel; while from the great toe inward the line is drawn toward the instep and thence in and outward curve to the heel. In one series this curve is deeper, showing a slightly different form of sandal. The average length of the stride is two feet three inches. The distance between the feet or the straddle is 18 inches, as measured from that center of the sandal of one foot to the center of the corresponding one.

"As before stated, these mammoth footprints were of an average depth of five inches, and had been made in a layer of sediment which is

middle toe from heel, five inches. The transverse diameter of the expanse of the foot, from the extremity of the inner toe, to that of the outer one, seven and a half inches. Step 23 to 24 inches. Another track has a rudimentary toe one and a half inches long, middle toe five and a half inches long, the expanse of the foot eight and a half inches. Step about the same. A round track five inches in diameter, made apparently by some animal of the feline species, is seen going south, and across the human tracks. They are 16 in number. There are also three or four small tracks, made by a wolf or some such animal, and a few deer tracks. All of the above-mentioned tracks are found on the

Series No. 6 has 15 human (?) tracks about the same size as the last; they are going northeasterly, and cross No. 5 about 24 ft. from the west wall. Bird tracks, covering 28 ft. of canvas, cross series No. 2, 3 and 4. These are all shown in diagram No. 2. But there are many more tracks on this floor, both human and animal, that we have not been able to represent. I was instructed by the Academy to take photographs of anything necessary to show the foot-prints and surroundings (eight photographs were taken by C. E. Peterson), also to take measurements, which I did by using two tape lines stretched 18 inches apart, and taking the distance to the center of the heel and toe of each foot. But see:

a fossil jaw of an elephant has been found; fossil teeth of the horse have also been found. Prof. Le Conte inclines to the belief that the supposed human tracks were made by a quadruped, and says: In conclusion, then, the one strong argument for the bi-pedal theory is the apparent singleness of the tracks and the absence of the toe marks, while the one strong argument for the quadrupedal theory is the wide space between the right and left series of tracks. To this may perhaps be added also the size and shape. It seems to me that inductive caution requires that the judicious mind should hold itself in suspense awaiting more evidence. Meanwhile, however, my own mind incline

PREHISTORIC FOOTPRINTS AT THE CARSON QUARRY. DIAGRAM NO. 1.

now so firmly consolidated as to retain a tolerably distinct external outline of the foot of the animal, but owing to the irregular formation of the calcareous deposit referred to, no distinct imprint of the bottom of the foot can be traced.

In the prison yard at Carson besides the above described tracks, those of birds are found in abundance. Most of these tracks show but three toes; in some instances, however, there are distinct impressions of four. The extreme length of the longest toe in any one of these bird tracks is five inches, and the stride meas-

first or upper floor, at the east side of the quarry; and many of them are shown in diagram No. 1.

"Series No. 2 consists of 13 human foot-prints 21 inches long, and 7 inches wide, going in a southwesterly direction until lost in the sandstone bluff at the south wall, which is 22 ft. high at this point. This man had a very peculiar shaped foot, and may be said to have toed the mark, he walked as straight as a surveyor running a line. The quarry is now being worked at this bluff, and we may soon expect more foot-

ing from the nature of the shale formation that the tracks were liable to be destroyed, it occurred to me to obtain copies of the foot-prints on canvas, which I did by marking the outline of the bottom of each track with plumbago, and rubbing the cloth on it, took the impression of each in the proper position, using 90 yards of cloth, and could have made use of as much more if time had been allowed. The foot-prints were photographed by spreading pulverized charcoal on the bottom. But if I had followed the outer edge of the displaced mud, it would have made

strongly to the latter theory. Since writing the above I find that Prof. Cope, in American Naturalist, vol. 16, p. 195, and Prof. Marsh, in a letter to me, regard the strata of Carson Quarry as belonging to the *Eocene Beds*. The age of these beds is still doubtful, some regarding them as upper Pliocene, others as early Quaternary. They are probably uppermost Pliocene. The Carson strata, therefore, are possibly deposits from King's Lake Shoshone, and not Lake Lahontan. From deposits of this age three species of gigantic ground sloths are

PREHISTORIC FOOTPRINTS AT THE CARSON QUARRY. DIAGRAM NO. 2.

ures a little more than two feet. Several very distinct tracks of a deer are to be seen, as well as those of a horse, the imprint of which is the same as that of the horse of to-day. Still other tracks, resembling those of a wolf, may be traced for 20 feet or more, when they also are lost in the cliff; and near the western limit of the quarry there are indications of a large animal having wallowed in the mud.

Diagram No. 3—On a smaller scale is made to represent a portion of the east, west and south walls of the quarry, so as to show at a glance the different series of tracks in their relative position. The lines run are magnetic.

In Mr. C. D. Gibbs' paper are the following notes of interest: Besides the tracks above mentioned, there are numerous others of wading birds, some having but three toes. Length of

prints to be found. This series covers 40 ft. of canvas.

"Series No. 3 contains 15 human tracks, 18 inches long and 7 wide, going nearly west; with the toes turned out, and stepping rather irregular."

"Series No. 4 has 14 tracks 18 inches long, going nearly parallel to No. 2, and crossing No. 3. It covers 40 ft. of ground.

"Series No. 5 extends over 112 ft. of ground and contains 44 human (?) foot-prints 18 inches long and 6 inches wide. But 5 tracks, from 19 to 25, are not distinct enough to represent, the shale, being destroyed by carts handling off the rock. These tracks are irregular in their direction, and disappear under the west wall, which is 32 ft. high."

them three or four inches longer, and four or five inches wider. (Engravings from photographs appended).

Of the photographic views shown, No. 1 is a continuation of east wall to mammoth tracks and tracks of supposed hyena.

No. 2—East wall at foot-prints of series No. 1, and tunnel.

No. 3—View from No. 4, showing No. 5 and portions of south and west walls.

No. 4—Bluff 22 feet high at guard-house No. 5, showing the stratum or upper beach in which the shells *Anodonta* and *Physa* are found. Also the stratum between the floors. The assistant is represented in the act of taking an impression on cloth of the hind tracks."

There is no doubt whatever about the elephant tracks. Since the excavations were made

known, viz: Two species of *Morotherium* and one species of *Myiodon*. It is not at all improbable, as suggested by Marsh in his letter, that the supposed human tracks were made by one of these. The size, the stride, the curve and the straddle all agree with this supposition.

CERTAIN telephonic experiments at Havre have resulted so favorably that it is now proposed to establish a regular system between that city and the various vessels at anchor. A pontoon structure, which will form the floating terminus of this curious system of marine communication, will be placed at some distance from the land, and neighboring vessels will send their messages to it.

MILL AND MINING MACHINERY.

F. A. HUNTINGTON,

No. 45 Fremont Street, - - San Francisco, Cal.

Oscillating Stamp Mill.

It has no Stems, Cam, or Tappets, and adjusts itself to the wear of the Shoes and Dies.
For simplicity, economy, durability and effective working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power. Awarded First Premium and Medal at Mechanics' Fair, S. F., 1880.

Manufactured by
F. A. HUNTINGTON, FRASER & CHALMERS,
45 Fremont St., S. F., Cal. | 145 Fulton St., Chicago, Ill.
Improved Patent Grinding and Amalgamating Pans, Concentrators and Gold Amalgamators; also, Steam Engines and Mining Machinery of all kinds. Send for circulars.

F. A. HUNTINGTON,
45 Fremont Street, San Francisco, Cal.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

Send for Circulars.

SHINGLE MACHINE.

For simplicity, durability and rapidity of action, these Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

SAWMILL MACHINERY,

Of all descriptions made to order.

IMHAUSER'S

Watchman's Improved Time Detector,
WITH SAFETY LOCK ATTACHMENT.

(Patented 1875-G 7-80-81.)

Beware of imitations. This instrument is supplied with 12 keys for 12 stations. Invaluable for all concerns employing night watchmen. Send for Circulars to

DUNHAM, CARRIGAN & CO.,

San Francisco, - - California.

THE SHEEP HOLDER

Saves money and labor and prevents the poor dumb animal from being cut or hurt in any way. When the animal is injured the flesh becomes impoverished, this causes a decrease in the quantity and quality of the fleece. The holder is also intended and adapted to holding the Angora goat while shearing, and is also useful while spotting or doctoring sheep or goats.

While a man shears one without the holder he can shear three with it, and not have to exert himself half so much, and, when his day's labor is over, he does not feel half so tired if he uses the holder; it is so simple in its construction, easily adjusted and takes but a moment to place the sheep or goat in position to be sheared and released in an instant. A boy twelve years old can easily shear with the holder. Patented by

CLAIRESSA BENNETT COOK,

212 KEARNY ST., SAN FRANCISCO, CAL.

County Rights for Sale.

Contains no Nitro Glycerine or Chlorate of Potash, and is the only High Explosive Manufactured in America that does not contain these Dangerous Ingredients.

Price of Tonite Materially Reduced for 1883.

TONITE POWDER CO.,

No. 327 Pine Street, - - - SAN FRANCISCO.

THE ROLLER ORE FEEDER.

Patented May 28, 1882.

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required.
In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

Golden State and Miners' Iron Works,
Sole Manufacturers,
237 First Street, SAN FRANCISCO, CAL.

BUY LAND

Where you can get a crop every year; where you will make something every season; where you are sure of having a crop when prices are high; where you have a healthy place to live; where you can raise semi-tropical as well as other fruits; where you can raise a diversity of grain and vegetables and get a good price for them. Go and see the old Reading Grant (in the upper Sacramento Valley), and you will find such land for sale in sub-divisions to suit purchasers—at very low rates and on easy terms. There are 12,000 acres at from \$3 to \$30 per acre, including pasturage, vine, fruit land and grain land. Will sell the whole tract at a great bargain. Send stamp for map and circular to EDWARD FRISBIE, proprietor, (on the Grant), Anderson, Shasta Co., Cal.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homaestic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - - San Francisco, Cal.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

-OR-

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiere & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ore is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

DEWEY & CO'S SCIENTIFIC PRESS PATENT AGENCY.

(ESTABLISHED 1830.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

A. T. DEWEY.

W. B. EWER.

GEO. H. STRONG.

Notes from Eureka, Nevada.

(CONTINUED FROM PAGE 134).

being run to cut through all of the different ledges, which enters the mountain at its base, near the valley level. It is now in 700 ft, and will be carried 7,000 ft to its terminus. There are three other tunnels being run at different points. In one of these work is being done to develop the mammoth ledge at a point where the vein is nearly ten feet thick, the average thickness of the same being five feet. The surface croppings on some of these ledges are quartz, and on others iron and low grade carbonate ore.

The ore runs from \$25 to \$80 for the second class and \$100 for the first class, and all of it averaging from 30 to 40 % lead.

One of our great necessities is

Additional Railroad Facilities.

which we are promised will shortly be secured for us.

March 2, '81, the Nevada Legislature passed a bill granting a franchise to the Eureka & Colorado River railroad giving right of way from Eureka to the town of Colville, on the big bend of the Colorado river. The franchise, together with a large block of the stock, was subsequently sold to the Denver & Rio Grande railroad company, who broke ground and commenced grading for the new road during the month of August, 1871, and the same has been completed, and ready to lay the track to the edge of Newark valley, near to the southern end of Silverado mountain. On account of the high rates of freight charged by the C. P. R. R. and U. P. R. R. for transportation of rails and construction material, the company express their intention of building from the east end of the road. It is said that they will commence laying rails this spring from Salt Lake, and that trains will be running from that place to Cherry Creek, 75 miles from Eureka, by next August. The line of the E. & C. R. R. leave Eureka by way of the Italian Rancho, crosses the Diamond range of mountains at the head of Pinto creek, thence runs north easterly to the point of Pancake mountain; thence southeast, to a gap in the White Pine range, six miles north of Hamilton, making the distance from Eureka to White Pine about 38 miles. The general direction of the line is east and west. It passes through the most extensive mineral, agricultural and stock-raising country in eastern Nevada. The way tributes to the road in this section of the State will be of almost every conceivable kind, not the least amongst which will be the immense ore and charcoal supplies to the Eureka furnaces. As Eureka has all of the elements for the fluxes required in smelting base ores, such as silica, limestone, iron, galena, etc., this new railroad will be the means of making it a great smelting center. The mining camps of Silverado, Newark, White Pine, Bald mountain and other localities along the line of the road will ship their ores to Eureka for reduction, the excessive rates of transportation, by team, being the only drawback to the successful mining of low grade ores at those places at the present time. High grade ores are now shipped from these camps to the Eureka furnaces, but only in small quantities, as the cost of mining them is too heavy to be made profitable. Railroad transportation of supplies to, and ores from the mines, will lessen the cost of production and carriage to such an extent, that even the low grade ores may hereafter be mined extensively and made to pay large profits.

M. H. JOSEPH.

Eureka, Nev., February 19th.

The Silk Culturists.

The California Silk Culture Society held its regular meeting on Thursday of last week, at the Academy of Sciences. The new president of the association, Mr. W. B. Ewer, read an introductory address, briefly reviewing the past efforts of the association, and offering some encouraging remarks in regard to the future.

It should be more generally known that it was through the efforts of this society at the Philadelphia Centennial, in making a practical display of the work of silk reeling, and of California raised cocoons and raw silk, that the present general movement in the Eastern States was inaugurated. From that small beginning, several large and influential societies have been organized in Philadelphia and elsewhere, through whose encouragement silk growing has received an impetus, and reached a measure of success, which bids fair to grow into an important national industry all through the Middle, Southern and Southwestern States. The labors of these societies have been greatly encouraged by liberal aid from wealthy citizens; hence, greater results have been met with there than in California.

In view of these facts, and of the further fact that California is so much better suited to this industry than the Eastern States, the California society has prepared and published a memorial to the Legislature asking for State aid in their efforts. This memorial will be found on another page, and fully explains itself. It also furnishes a substantial argument why such aid should be extended.

The meeting on Thursday was mainly devoted to a consideration of the memorial, and the ways and means for having it properly brought to the attention of the Legislature, to which body it has already been presented. A commit-

tee was appointed to go to Sacramento to look after that matter.

New members are being constantly added to the society, the regular meetings of which are held upon the first Thursday of each month. The society has silkworm eggs for sale, and is willing to give them away in small quantities to those who are unable to buy, or to such as may desire to experiment in a small way.

Floods and Forests.

The associated press dispatches during the last week from valleys of the Mississippi and its tributaries have been filled with heartrending details of suffering and loss of life and property by floods, which have been higher than ever before in the history of those regions. Thousands of people have been driven from their homes in Cincinnati, Louisville and a host of other towns built upon the banks of the Ohio river, bridges have been swept away and other towns submerged in nearly all the States of the great valley, communication has been interrupted, hardship and suffering have been reported on every hand. The vast volume of water has burst the levees in the lower parts of the Mississippi and flooded towns and agricultural lands. Millions of property have been destroyed, homes overwhelmed, lives lost, and the prosperity and comfort of thousands arrested by angry waters. Generous contributions of money and supplies for the sufferers have shown the tender heart of the nation. The question, however, arises, whence the cause of this unusual visitation; are the people to be at the mercy of its recurrence, or can something be done to check the preceptitious downpouring of the waters in the future. In the midst of the columns of news about the ruin caused by the waters we find the following key to the situation. Murat Halsted, a prominent citizen of Cincinnati, calls attention to the remarkable similarity between the flood in the Ohio river and the recent floods in the Rhine and the Danube. General McClellan, in an interview, says: As a preventive against another flood, the nation must enact laws similar to those in Europe, compelling the replanting of trees as fast as cut off.

This is undoubtedly the secret of the unprecedented rise of the waters in the valley of the Ohio, and it will for years be subject to similar visitations before any remedial measures can reach an effective condition. The denuding of the vast watersheds of the Ohio and its tributaries has been in progress for years, and a condition has at last been reached when the water from the rainfall and melting snows rushes in a body into the water-courses from the naked slopes instead of seeping down through porous forest soils until the surplus not required by the growth of vegetation, gradually finding its way to the ocean. Water rushes from bare hillsides as from a roof; it is held by forest-covered soil as from a sponge, and only on super-saturation does the excess slowly find its way to the lower levels. What has been gained and what lost by the change, and how can the ills of the present condition be obviated? Let a speaker at the recent Forestry Congress at Montreal state the case as we find it reported in the *American Journal of Forestry*:

"We have gained to agriculture for pasturage and for cultivation, a large area of fertile land in the emptied basins of the old reservoirs and mill dams. We have gained pastures and farming lands on the hills. We have gained in the aggregate productions of the region and in population by extending the cleared land. On the other hand we have subjected ourselves to cloud-bursts on the naked hills, which once drank in the descending floods in the porous woodland soils, but now the solid, compact hillsides throw off the floods into the valley at times an irresistible torrent, carrying destruction and death in its course. We have lost in the destruction of untold millions of feet of lumber, sold at prices low compared with present rates, with vast amounts of wood recklessly destroyed; and when we consider the fact that, as a result of our interference with the restorative operations of nature, we have stamped out all prospect of the renewal of forest growths by close pasturing and continuous plowing, it is indeed a question whether we have not lost instead of having gained by the change. Not that we would regain all the land in woods again were it in our power; but by judicious replanting of the waste lands where the woods have been destroyed, the steep and rocky hillsides and ravines that possess but little value for agriculture, we might establish the happy equilibrium, preserve and restore the springs and feeding rills, and prevent a further diminution of the stream. Keep up the proper balance of woodland and tillage, which preserves, in a measure, greater uniformity of climate, humidity and rainfall, while all the time, and for all time, the land so appropriated and occupied will be yielding a rapidly increasing capital and a paying investment in the production of the timber.

How can this work of replanting be done? By the awakening of the whole people to the need of it; by inculcating the advantages of tree planting; by arousing individual and governmental interest and resolutely going to work to secure the desired results. The American Association for the Advancement of Science at a recent session adopted a memorial to Congress which covers many directions in which valuable encouragement can be given to tree-planting. It asks that roadside tree planting be encouraged by deducting the cost from road taxes; that land planted to forest trees be ex-

empt from increased valuation by the Assessors because of the trees; that State money be appropriated for horticultural societies to offer as premiums for successful tree planting and care; that prizes be offered for the best and most practical essays on the subject; that educational institutions be encouraged to establish instruction in silviculture; that laws against wilful or careless forest firing be enacted; that model plantations be undertaken at State expense, and persons trained in forestry; that State Forestry Commissions be established in every State, etc.

Never before did measures of this kind force themselves upon the public attention as at the present. No time should be lost putting forth efforts to preserve existing forests and in replanting every spot in the thickly populated States, which can be spared from regular crop tribute. Let each one consider it his or her duty to do something towards the ends desired.

SUFFER

no longer from Dyspepsia, Indigestion, want of Appetite, loss of Strength, lack of Energy, Malaria, Intermittent Fevers, &c. BROWN'S IRON BITTERS never fails to cure all these diseases.

Boston, November 26, 1881.

BROWN CHEMICAL CO.

Gentlemen:—For years I have been a great sufferer from Dyspepsia, and could get no relief (having tried everything which was recommended) until, acting on the advice of a friend, who had been benefited by Brown's Iron Bitters, I tried a bottle, with most surprising results. Previous to taking Brown's Iron Bitters, everything I ate distressed me, and I suffered greatly from a burning sensation in the stomach, which was unbearable. Since taking Brown's Iron Bitters, all my troubles are at an end. Can eat any time without any disagreeable results. I am practically another person.

Mrs. W. J. FLYNN.

30 Maverick St., E. Boston.

BROWN'S IRON BITTERS acts like a charm on the digestive organs, removing all dyspeptic symptoms, such as tasting the food, Belching, Heat in the Stomach, Heartburn, etc. The only Iron Preparation that will not blacken the teeth or give headache.

Sold by all Druggists.

Brown Chemical Co.
Baltimore, Md.

See that all Iron Bitters are made by Brown Chemical Co., Baltimore, and have crossed red lines and trade-mark on wrapper.

To Prospecting Quartz Miners.

Miners having reliable properties in California, and who are willing to give one-half of their interest in the same for suitable machinery, may benefit themselves by corresponding with me. Now wanted on this lay: A decomposed quartz lode, where water can be had for power; also a mine sufficiently large and developed for a 10 Stamp Mill. Address,

ALMARIN B. PAUL.

Room 20, Safe Deposit Building, San Francisco.

Dewey & Co., American and Foreign Patent Agents.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agent, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our employ, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

PATENTS AND INVENTIONS

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in Dewey & Co.'s Scientific Press Patent Agency, 252 Market St., S. F.

WEEK ENDING FEBRUARY 6, 1883.

- 271,792.—STONE DRILLING MACHINE—Jas. T. Clark, Bath, Cal.
 271,793.—INSOLE FOR BOOTS AND SHOES—E. K. Cooley, S. F.
 271,687.—WATER, GAS OR DRAIN PIPE—John P. Culver, Tucson, A. T.
 271,813.—EVAPORATIVE COOLER—Geo. W. Deitzler, S. F.
 271,821.—APPARATUS FOR PURIFYING WATER FOR BOILERS—Chas. Elliot, S. F.
 271,695.—STOCK CAR—Job C. Foster, St. John Cal.
 271,847.—SCREEN CLEANING DEVICE—Thos. Holman, Salem, Oregon.
 271,709.—HAMMER—H. O. Hooper, Fresno, Cal.
 271,853.—BOLTING REEL—J. D. Hurst, Salem, Oregon.
 271,710.—DRIVING CART—E. Hutson & E. Squires, Salem, Oregon.
 271,713.—COUPLING LINK—William M. Jones, Stockton, Cal.
 271,630.—BAG HOLDER—W. E. Shellenberger, Woodland, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and foreign Patent Agency, the following are worthy of special mention:

COUPLING LINK. Hilliard M. Jones, of Stockton, California. No. 271,713, dated February 6, 1883. This invention relates to a new and useful coupling-link, and it consists in a metal ring or link with separated ends, in one of which a peculiar latch is pivoted or hinged, the other end of which is adapted to fit into and be secured in a socket in the other end of the link. The object of this invention is to provide a convenient, effective and economical device for coupling any desired number of chains. The special object is to adapt it for use in harness in coupling side and fifth-chains of the forward team to the fifth-chain of the team behind.

STOCK CAR. Job C. Foster, St. Johns, Colusa Co., California. No. 271,695. Dated Feb. 6, 1883. This invention relates to certain improvements in that class of railway-cars used to transport live stock, and known as "stock-cars." The object of this invention is to provide a car in which live stock may be transported and fed with convenience and dispatch during the continuance of the journey without having to leave the car.

WATER, GAS, OR DRAIN PIPE.—John P. Culver, Tucson, Arizona Ty. No. 271,687. Dated February 6, 1883. This invention relates to that class of pipes which are composed of thin iron sheets or other suitable metals, having a layer of asphaltum interposed between the layers of iron, so that when properly formed the asphaltum will fully preserve the iron.

EVAPORATIVE COOLER.—George W. Deitzler, of San Francisco, Cal. No. 271,813. Dated February 6, 1883. This invention has reference to that class of coolers in which the reduction of temperature is produced by evaporation; and it consists essentially in devices and processes for delivering water to the evaporating surfaces automatically as needed, and so as to prevent waste.

HAMMER.—Henry O. Hooper, of Fresno, California. No. 271,709. Dated February 6, 1883. This invention relates to that class of hammers adapted to hold nails by their heads while being started into the material in which they are subsequently to be driven.

REDLANDS.—According to all reports, Redlands colony, in San Bernardino county, is progressing very satisfactorily. The elevation has been found a great advantage during the cold winter, effects of frosts being less than in most other localities. The march of improvements has been kept up, and tree planting and home-making have kept the many colonists busy. All visitors are charmed with the beautiful situation of the lands and other superior advantages. Those seeking homes in the southern country should not overlook the claims of Redlands.

Complimentary Sample Copies of this paper are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give their own patronage; and as far as practicable aid in circulating the journal and making its value more widely known to others and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year.

N. B.—Personal attention will be called to this (as well as other notices, at times) by turning down a leaf.

An Improved Time Detector.

We illustrate on this page Imhanser's improved watchman's time detector with safety lock attachment. The marking apparatus in these instruments is placed in the cover of the case, separately from the watch movement, which is thereby protected from injury by dust getting in through the key-hole. This is a great advantage over ordinary watchmen's clocks, having the marking springs for pricking holes on the dial not separated from the time movements.

The safety lock attachment is a recent improvement of great importance, being a safeguard against tampering with the record. It consists of a stationary knife placed inside the cover in such a position that every time the cover is closed or opened the edge of the dial card is cut, making a nick on the rim about one-eighth of an inch deep, and showing the exact time when so cut. From the number of the cuts and their time, it will be easy to detect any tampering by opening the cover. Without this attachment, any detector would not be ascertained against false records by dishonest watchmen.

With the watch there are 12 different keys, which are fastened one at each post where the watchman is to call during his round. Keys, Nos. 1 to 6, mark a figure between the circles 1, 2, 3, 4, 5, 6 on the dial cards, and keys Nos.

Imhanser's Time Detector.

7 to 12 mark a figure on the lines of the circles, so making a clear registration, not a confused one as is the case with other detectors having records made by punching holes in the dial card.

The watchman entering upon his duties in the evening receives the detector locked and in the leather pouch. The watch is previously wound and supplied with a fresh dial card, care being taken to place the nut on the arbor in the center, according to the marks on the nut and arbor. The watch will run about 60 hours.

Arriving at any station, the watchman inserts the key he finds fastened there, through the pouch into the key-hole on the rim of the watch opposite the ring, and turns the key round to the right once, and withdraws it; a figure will be stamped on the dial in such a position as will show the precise time of the registration.

On delivering the watch in the morning, the person in charge can see at a glance how often and when the rounds have been made during the night; whether every station has been visited or any neglected, what space of time elapsed between the different visits, etc.; in short, it tells the history of the night's doings of the watchman.

With a faithful watchman, the risk of loss, either by robbery or fire, is reduced to the minimum; but how to know that the watchman is faithful is the question; for a watchman who deserts his post, or "sleeps on guard" is worse than none at all. The agents in San Francisco for these appliances are Dunham, Carrigan & Co.; and they are in use by a number of firms of this city.

New Incorporations.

Esmeralda Copper Co., Feb. 21. Capital stock, \$2,500,000. Directors: Angus C. McAfee, Frederick Conn, DeWitt T. Biber, John Conry and Hiram D. Tuttle.
Union Iron Works, Feb. 20. Capital stock, \$2,000,000. Directors: Geo. W. Prescott, Irving M. Scott, J. O'R. Gunn, Geo. W. Dickie, H. L. Markey and George Fredericks.
Amargosa Borax Co., Feb. 21. Capital stock, \$50,000. Directors: William Locke, William C. Brown, Thomas W. Chion, George Rouner and William R. Townsend.

SENATOR TAYLOR'S bill amending the bullion tax law, so as to make it what it purports to be, "a tax on the net proceeds of mines," was defeated by a large majority in the Nevada Senate.

REMARKABLE for overcoming diseases caused by impure water, decaying vegetation, etc., is Brown's Iron Bitters.

Our Agents

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. McGREW—Santa Clara county.
 M. P. OWEN—Santa Cruz county.
 J. W. A. WRIGHT—Merced, Tulare and Kern counties
 J. R. C. HOAG—California.
 B. W. CROWELL—Los Angeles and San Bernardino counties.
 L. WALKER—Sacramento, San Joaquin and Stanislaus counties.
 N. H. HARRISON—Plumas county.
 A. C. KNOX—Santa Clara county.
 M. H. JOSEPH—Eureka, Nev.
 GEORGE McDOWELL—Sonoma and Mendocino counties

News in Brief.

THERE will be a narrow gauge railroad into the northern mining camps from Theson.

THE improving effect of the late rains is made manifest by the rapid growth of grain in the State.

FOUR more cadet officers were reduced to the ranks at Annapolis, Saturday, for recent acts of insubordination.

A POLE has been sentenced by a French court to two years' imprisonment for threatening to murder President Grevy.

OSCAR WILDE, it is said, will return to this country in the summer to superintend the production of a play which he has written.

THE Maine House, 104 to 37, ordered en masse the prohibitory amendment. An attempt to except cider failed by a vote of 56 to 80.

A CHICAGO inventor of a rope fire escape, who refused to give his name, tried his apparatus Saturday morning, and sustained fatal injuries.

THE Fire Commissioners, of Buffalo, have ordered all hotels to place balconies on each floor and connect them by single ladders, under penalty of fine.

TWO hundred or more gambling and policy shops in Boston closed their doors Wednesday week, in consequence of an order by the Police Commissioners.

THE theory that tramps set fire to the New-hall house, Milwaukee, is now advanced. It is said they frequently sneaked into the coal cellar for a night's lodging.

THE New Orleans *Picayune* asserts that the death rate has increased at Memphis since the completion of the sewer system, and seems to prove it by statistics.

A BILL has passed the Arkansas Legislature prohibiting for two years the sale of intoxicants within three miles of any church or school, on petition of a majority of adult inhabitants.

BARTHOLOMEW's statue of Liberty is nearly completed. It is to be a free gift from France to the United States, and as yet the subscription to the pedestal is not sufficient to pay for a corner stone.

San Francisco Metal Market.

*Reports missing.

THE MEMBERS of the Ladies' Cooking Society, of San Francisco, held a most interesting and instructive meeting this week. The subject under discussion was the purity and relative value of the various baking powders now on the market competing for public favor. After an animated and extended interchange of views had taken place, samples of the various brands were produced and their purity put to the well known boiling test. A small quantity of each powder was placed in a little water and boiled for a few minutes. Those powders that were adulterated with starch or flour made a fair article of paste when put through this ordeal; those drugged with ammonia were detected by the odor of the paste when warm, while the New England, composed of cream of tartar and soda only, simply dissolved and, after settling, left the water perfectly clear. The New England Baking Powder passed all these tests and practical trials with entire satisfaction, and the whole assembly of ladies united in its praise.

Easy Binder.

Dewey's patent elastic binder, for periodicals, music and other printed sheets, is the bandiest, best and cheapest of all economical and practical file binders. Newspapers are quickly placed in it and held neatly, as in a cloth-bound book. It is durable and so simple a child can use it. Price, size of Mining and Scientific Press, Rural Press, Watchman, Fraternal Record, Home Journal, Harper's Weekly, and Scientific American, 75 cents; postage, 10 cents. Postpaid to subscribers of this paper, 50 cents. Send for illustrated circular. Agents wanted.

Type for Sale.

15 Cts. per lb.

About 1,000 lbs. of Scotch brevier type used on this paper previous to Jan. 13th, 1883, will be sold in lots of 100 lbs., or more, for 15 cents per lb., and cost of boxing and shipping, if applied for soon. Apply to Dewey & Co., Publishers, No. 252 Market St., S. F.

New Sheet Music.

Quite a variety of songs and pieces appears among the newest publications of Dison & Co., just received. First there is a quaintly pretty "go-pel song," by Bonar, "Is this all?" (30 cents), made into an accepta'ble sacred quartet by C. W. Green. Then we have "Voices" (30 cents), a melodious song by Birch; "Oh, You Little Darling" (30 cents), in popular style, by Tabran; "Laughing Old Farmer Mace" (35 cents), comic song by Newhall; "Invitation to the Waltz" (50 cents), for violin and piano, by Winner; "Lexey Glen Schottische" (30 cents), by S. M. Tod; "Album L'at" (30 cents), piano piece by Lange; another quite different "Album Leaf" (30 cents), by Seelman, and good plantation song, "When the Ole Man is laid away" (30 cents), by L'Orange.

Agents Now Wanted.

Extra inducements will be offered for a few active canvassers, who will give their whole attention (for a while at least) to our business. Apply soon, or address this office, giving address, age, experience and reference.

DEWEY & CO., Publishers.

No. 252 Market St., S. F.

A Cheerful Recommendation.

BENICIA, CAL., February 4, 1883.

Messrs Dewey & Co., Patent Solicitors:—I am in receipt of my patent, "Improvements in Vehicle Brakes," obtained through your Agency, and would say I am much pleased with thorough and graphic description in specifications and drawings, and can cheerfully recommend you to anyone wishing to obtain favors in your line.—Truly yours, G. R. DRYAL.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arseniurets, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequalled by any other published embracing the subjects treated. Post-paid, \$7.50. Printed and sold by Dewey & Co., S. F.

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition, 1880), and the Extraction of their Respective Metals without Quicksilver. Illustrated. 156 pages. A valuable and carefully written work. Postpaid, \$3. Sold by Dewey & Co., S. F.

AARON'S LEACHING GOLD AND SILVER ORES.—The most complete hand-book on the subject extant, 164 pages octavo. Illustrated by 12 lithographic engravings and four woodcuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by Dewey & Co., S. F.

PHILLIPS' EXPLORERS' AND ASSAYERS' COMPANION (Third Edition). Price of Vol. 1, post-paid, 56 Sold by Dewey & Co., S. F.

COPP'S AMERICAN MINING CODE, to replace Copp's Handbook of Mining Laws, now out of print. United States, State and Territorial Mining Laws and Land Office Regulations; Digest of Land Office and Court Decisions; List of Patents Issued, and Dr. Raymond's Glossary with Form for Mechanics' Liens, Location Notices, etc. Price, postpaid, in paper, 50 cts. Sold by Dewey & Co., S. F.

THE EXPLORERS' MINERS' AND METALLURGISTS' COMPANION, by J. S. Phillips, M. E., comprising a practical exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy, containing 672 Pages and 83 Engravings. Price, bound in cloth, \$10.50. Sold by Dewey & Co., S. F.

U. S. MINING LAWS AND COAL LAND LAWS—Containing instructions and blank forms. Postpaid, 50 cents. Sold by Dewey & Co., S. F.

MINING, ENGINEERING, MECHANICAL, FARMING, SCIENTIFIC, INDUSTRIAL AND NEW BOOKS in general can be ordered through Dewey & Co., publishers of the MINING AND SCIENTIFIC PRESS, S. F., at publishers' rates.

This paper is printed with Ink Manufactured by Charles Eneu Johnson & Co., 509 South 10th St., Philadelphia. Branch Offices—47 Rose St., New York, and 40 La Salle St., Chicago. Agent for the Pacific Coast—Joseph H. Dorey, 529 Commercial St., S. F.

"Abel Stearns RANCHOS."

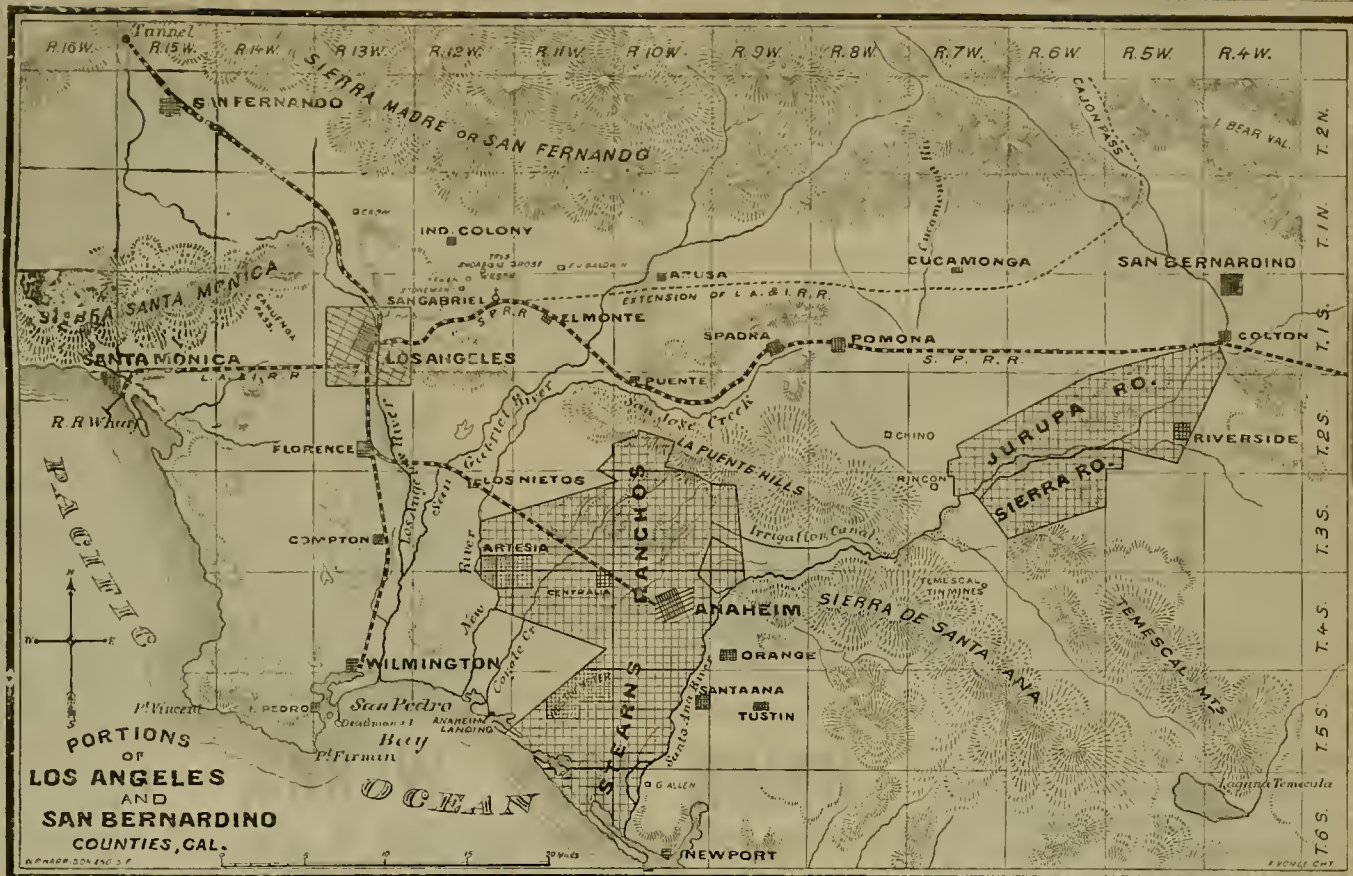

The Center of Los Angeles Valley.

Embracing Anaheim, Westminster, Artesia, Garden City, etc. Thirteen miles southeast of Los Angeles City, within the Artesian Well Belt. Hundreds of flowing pipe wells. Water near the surface. Rivers on two sides; ever-flowing creek runs through the tract. Front on the Ocean. Transportation and passage by Steamships or Railroad. Southern Pacific Railroad through the tract. Twenty-one hours from San Francisco. The new land for sale or lease in sections or fractions. Apply to Trustee A. ROBINSON, 318 California St., San Francisco.

Or to ROBERT J. NORTHAM, Anaheim, Cal., or concerning Westminster Colony, to REV. ROBERT STRONG, Westminster, Cal.

Terms, one-fifth cash, balance on interest at 10 per cent. per annum.

Send for Circular and Map.

Redlands.

Good water, rich soil and magnificent view. High elevation, dry air, few fogs and northerers.

No brush or fence on the land, which is especially adapted to the culture of the orange and raisin grape.

Near to church, school, store and depot. Hotel open. Telephone Communication.

Stage from San Bernardino Tuesdays, Thursdays and Saturdays.

The price of land has steadily advanced from the first price of \$50 per acre until now it is held at \$200 per acre.

653 & 655 Mission St., San Francisco, Cal. E. G. DENNISTON, Proprietor.

Good Land and Sure Crops.

There has been steady and tolerably rapid advancement made in the growth of a majority of the towns in Colusa, Butte, Tehama and Shasta counties. Especially is this so in the agricultural districts where the land produces at least fair crops in all seasons—wet or dry—as does the land on the Reading Ranch. Those looking for homes in California where diversified farming will pay every year; where wood and water are plenty and easy to be obtained, and other desirable advantages are to be had, should address the proprietor of the Reading Grant.

Some 14,000 out of 26,000 acres of the grant remain in sale at comparatively low rates, in quantities to suit purchasers, on easy terms. Prices range from \$5 to \$30 per acre. The tract is between two and three miles wide, with the Northern Division of the C. P. R. R. passing centrally through its entire length. Send postage stamp for free circulars containing information about Shasta County and these lands, to the proprietor of Reading Ranch. EDWARD FRISBIE, Anderson, Shasta County, Cal.

The Lemmon Herbarium

This Herbarium has been removed from the Blake House to a permanent place at 1205 Franklin St., near Fourteenth St., Oakland, one square east of the Post Office, where plants of the Pacific Coast, including Arizona, may be determined on application, and instruction given in botany during the winter. Sets or single specimens of the rare and new ferns of the Pacific Coast for sale.

CHAS. E. LLOYD, J. S. BEARDSLEY, BEARDSLEY & LLOYD, REAL ESTATE AGENTS.

No. 912 Broadway Street, Between 8th & 9th Sts., Oakland.

Particular Attention given to Negotiating Loans upon Favorable Terms. Acting as Agents for Buyers and Sellers of Real Estate, and the Management of Business for Absent Owners.

COPPER.

SOME FACTS REGARDING THE YIELD IN 1882.

The Rankin & Brayton Pacific Copper Smelters—A Cheap and Effective Furnace for Reducing Copper Ores.

The copper mining interests of the country at large are of vast importance, statistics at hand showing an enormous increase in the yield of this useful metal during the past year. The yield of the Lake Superior mines during eleven months in 1882 was as follows: The Calumet & Hecla paid, in dividend, the sum of \$2,000,000; the Quincy, \$820,000; the Central, \$50,000; the Atlantic, \$50,000; the Osceola, \$250,000. The aggregate yield of these five mines for the eleven months ending November 31, 1882, was 21,400 tons of ingot copper, or a total in coin of \$2,900,000. The total dividends paid by these mines up to the date mentioned reached the sum of \$28,140,000.

This, however, is but a small proportion of the yield of copper during that period. Throughout the western States and Territories the exploitation and development of copper mines is steadily progressing, and we predict for the current year a yield that will greatly exceed—if it does not quite double—this amount.

In New Mexico the discovery of extensive veins of copper, in the Fra Cristobal and Caballo mountain districts, has given a fresh impetus to this important branch of the mining industry in that Territory.

In Montana, copper is found in paying quantities in nearly every portion of the Territory. Her yield, last year, was 10,000,000 pounds.

The product of Michigan, alone, was, in 1882, 51,500,000 pounds.

Arizona, where the copper interest is yet in its infancy, gave an output last year of 15,500,000 pounds.

Doubts have been expressed by mining men as to the reward which might await those who should undertake the development of the vast deposits of this mineral that are to be found so abundantly distributed throughout the West.

Owners of such properties need have no misgivings as to a profitable market for copper. The home consumption alone, last year, was 45,000 tons—but 140,000 pounds less than the entire product of the country.

The improvements in electrical appliances, and the many new uses for copper in the mechanic arts, will insure a profitable market for all that

our mines—old, new and yet to be discovered—may produce. One of the great electric lighting companies consumed, in 1882, 6,000,000 pounds. The exports during that period, in ingot copper, pyrites, mattes and miscellaneous copper products, is roughly estimated at 6,000,000 pounds. The demand for this metal, it may safely be said, is now in excess of the supply.

In the development of this important industry the use of machinery exactly adapted to the process of reducing the ore to a marketable condition is a highly important factor. In this the

Pacific Copper Smelter,

Manufactured by Rankin & Brayton, proprietors of the Pacific Iron Works of this city, is proved to be the best and most economical apparatus yet discovered. Indeed, the invention of the Pacific Water Jacket Smelter, made and manufactured only by the above-named firm, has entirely revolutionized the business of smelting, and made practicable the working of copper ores in all their various combinations.

This smelter is simple in construction; perfect in its operation. Its very low cost commends it to the consideration of all mining men, but more particularly those of limited means.

It Can be Run Continuously,

Without loss of time and without expense for repairs. It unfailingly gives the highest product at the smallest possible expense for fuel and attendance.

It is a fact, established beyond dispute, that no other smelting apparatus can compare with the Rankin & Brayton

Water Jacket Furnace

For practical and satisfactory results. Where all other smelting processes fail, the Pacific Copper Smelter proves equal to all that is required of it.

The whole structure is complete as it leaves the works, ready to set up, requiring no brick work, except a few courses for forming the crucible, and can, therefore, be put up ready for operation at small cost, and in a few days' time. The Jacket is made of heavy flange iron of the most enduring quality, and with much more care than is ordinarily given to any class of boiler-work.

Patent Circulating Plates

Are formed in the water space to insure a rapid circulation of the water. This device, by leaving no spot within the water space where the water is not in constant and rapid motion, causes the heat to be evenly distributed throughout the whole jacket, and thus prevents unequal expansion and contraction, and consequently leaky joints. The motion of the water also prevents any scale or sediment from depositing on the surface, and in this respect is of great advantage where water used is highly mineralized.

A High Degree of Economy

In the use of water is also attained by this device, as all the water introduced into the jacket is brought in contact with the heated surfaces, and

none escapes the over-flow without having absorbed all the heat possible. In many localities where water is scarce, this point is one of much importance. Experience has shown this to be the most valuable improvement ever made in Water Jacket Smelters, adding at least two or three times to the effective wear and service of the jacket, besides saving in loss of time and cost of repair.

The Arrangement of Tuyeres

Is such as to secure a perfect delivery of blast to every part of the charge, producing a uniform melting area throughout its entire section, thus obtaining rapid action of the furnace, great economy of fuel, and preventing any tendency to freezing. The tuyeres, being entirely within the water space of the jacket, are wholly protected from the action of heat, and consequently never burn out or become a source of trouble. Peer-holes, with removable cap and mica covering, are arranged opposite each one, so the processes going on inside the furnace can be constantly observed.

These furnaces invariably overrun their rated capacity. In many instances this is remarkable—a 20-ton smelter frequently running 30 to 35 tons in 24 hours. With most other machines for this purpose the reverse is too often the case. In no single instance has one of these smelters failed to give entire satisfaction; with sometimes results surprising to manufacturer and patron, alike—this fact being due largely to the perfect distribution of and application of the blast.

The Crucible

Is formed on a bottom, hinged to a plate that can be instantly dropped when any obstruction occurs, or for access to the interior when repairs are necessary.

The economy and facility with which these furnaces are operated makes it possible to profitably reduce ore of a much lower grade than has heretofore been thought practicable; and consequently the field for such enterprises has been greatly enlarged.

The great success of this smelter has induced various dishonest persons to imitate it. But the limitation does not extend beyond the general external appearance of the structure. Its many uniform advantages are peculiar to itself, and cannot be found in any counterfeit presentation of the original. The most valuable features are

Covered by Letters Patent.

No furnace similar to it can be made without infringing upon that manufactured exclusively by or under control of Rankin & Brayton.

These smelters are made of ten, twenty and thirty tons daily capacity. The larger size is recommended as the most desirable, when the ore development will warrant it, for the reason that the expense of running it is but little more than that of the smaller sizes.

The importance of this invention can not be over-estimated. It will prove a most important factor in the development of the rich veins of copper that are constantly being discovered in all parts of the country.

Mr. Brayton returned, a few days since, from an extended trip through the Eastern States. He comes back to us fully impressed with the growing importance of the copper production of the country, and while the construction of the varied machinery for the reduction of gold and silver will not be permitted to flag, special attention will be paid to the manufacture of the Pacific Copper Smelter and other appliances for working the products of copper mines.—S. F. Stock Exchange.

REDLANDS.

Good water, rich soil and magnificent view. High elevation, dry air, few fogs and northerly. No brush or fences on the land, which is especially adapted to the culture of the orange and raisin grape.

Near to church, school, store and depot. Hotel open. Telephone communication. Stage from San Bernardino Tuesdays, Thursdays and Saturdays.

The following information concerning one of the best-reputed and promising colony enterprises in Southern California, is from the Riverside Press, of San Bernardino County, April 1, 1882.

A Model Settlement.

"No place in California has sprung into public notice so rapidly and gained so deserved a reputation in so short a time as has the new tract of Redlands.

This tract is located between Old San Bernardino and Crafton, on the south side of Mill Creek ditch, and comprises 2,500 acres of as choice fruit lands as can be found in the State. The land is of a reddish clayey loam, not clayey enough to work hard, having sufficient admixture of sand to hold moisture and give the best results when planted to orchard or vineyard. The red lands of the State are everywhere celebrated as being superior for tree and vine.

The tract slopes to the northwest, and commands one of the grandest views to be found in the State. The track of the Southern Pacific railroad runs one and a half miles from the center of the Redlands tract, and a depot has been established for the accommodation of Redlands and neighboring settlements.

The Redlands tract is laid off by running avenues from northeast to southwest, one-quarter of a mile apart and cross streets at right angles to these avenues every half mile, thus cutting the tract into blocks, each of which contains 80 acres. The avenues are each 100 ft. wide. The cross streets are 60 ft. wide.

Town Plat

Near the center of the tract is a town plat, consisting of 140 acres, cut up into lots ranging from an ordinary business lot to two and a half and five-acre residence lots.

The Water System

Is one of the most perfect in the State. The water supply comes partially from the South Fork ditch of the Santa Ana river and partially from private water developments in the Santa Ana canyon and other localities. The waters are to be conducted to a large reservoir, located in a canyon adjoining the tract, and distributed from this reservoir by means of cement pipes. These pipes are so laid as to carry the water without loss to the highest point on each ten-acre lot. The basis of water supply is one inch of water, statute measurement, to each eight acres of land. This is ample, and up to the best irrigated tract in the State.

The orange, lemon, apricot, peach and raisin grape will grow here to perfection. Judson & Brown, San Bernardino P. O., owners of the tract, are energetic men, who leave no stone unturned to make their enterprise a success. They do not try to figure how little they can do and sell their land, but where they can put another thousand dollars and make the tract more desirable to first-class settlers. There is nothing shoddy about their operations. Redlands will stand in a few years as one of the finest settlements on the Pacific coast.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS.

All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

- No. 1.—The most Powerful Explosive Compound now in use.
- No. 2.—Surpasses in strength any Powder of its class ever manufactured.
- No. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much finer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 80% stronger than the strongest Nitro-Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same.

Placing Frue Concentrators.

The use of a revolving belt, either plain or with riffles or buckets, as a carrier for various materials is not of recent date, but the application of a lateral shaking motion to such a belt—a motion closely resembling that given to a shovel in ranning by hand—is a novelty, and constitutes the essential element of the success of the Frue concentrator. A revolving belt of canvas with a lateral or end blow has been used in Germany and England, and also in the States, and though pretty good results were obtained with it, the difficulty of making the belts last proved too great. The *side shake* is as great an improvement over the *blow* as the perfect rubber belt, with permanent high flanges, is superior to the rough, costly, short-lived canvas belt. The Frue concentrator, as now made, though so simple in its appearance and action, is the result of no small expenditure of thought and time, and has been evolved only after a process of variation and selection extending over a number of years.

Several hundred of these machines are now running in the mining regions on this coast, and doing good work. Perhaps the best recommendation that could be given for them lies in the fact that, in many places where they have been in use for some time, more of the same pattern have been ordered.

So well known are the machines that no description of this concentrator or operation is necessary, and the engraving in our advertising columns will show the appearance of the machine to those who have not seen it. There is sometimes some doubt as to the best place to put the concentrator, but the accompanying engraving will indicate this. The cut shows the position of the Frue concentrator (placed with its foot towards the battery), in a gold mill, where only one is used for five stamps; where two are used, the head of the second one is placed towards the head of the one shown.

The counter shaft to drive the Frue concentrators is placed parallel with the cam shaft and main line shaft of the mill. It is therefore placed at right angles to the crank shaft and pulley of the concentrator itself. This necessitates the use of a quarter-twist belt. The proper placing of this counter shaft and pulley is very important; for with it properly set the quarter-twist belt runs as well, as true and with as little wear as if it were a straight belt; while if not properly set it will run off the pulley. This placing of counter shaft and pulley for quarter-twist belt does not seem to be generally understood even by good mechanics, and we, therefore, give the above cut, illustrating the placing of this counter shaft; this will make plain the proper method; *a a* is the crank shaft of the concentrator; *b b* is the counter shaft; on *b b* are one tight and one loose pulley—the belt is shown on the tight pulley.

The rule is as follows:

"In placing the counter shaft and its pulley, the pulley should be set so that the side from which the belt leaves it is in line with the

square of the crank shaft of the concentrator at that point."

It will be borne in mind that the crank shaft is not horizontal. This engraving will serve as a guide to mechanics who want to use a quarter-twist belt with any mechanism.

THE Salt Lake Tribune gives a statement of

AN OLD MINER'S FATE.—On Wednesday the 14th inst., Robert Hammon, an old miner, about 56 years of age whose past history none of his neighbors knew anything of, was found dead in his claim near Marble Valley, where he was engaged in the old-time employment of panning

ARRANGEMENT OF SHAFTS AND PULLEYS FOR QUARTER-TWIST BELT.

PROPER POSITION OF FRUE CONCENTRATOR WITH RELATION TO BATTERY IN GOLD MILL.

the expenditures made in Utah Territory in 1882 by the various mines. The Horn Silver mine leads the list by a total expenditure of \$1,333,800. The Ontario follows with \$978,000. Six other claims have expended from \$200,000 to \$772,000. Eight more have disbursed from \$100,000 to \$181,300, and about 20 more have spent from \$10,000 to \$75,000. The list contains 35 claims or firms, and the total amount expended in 1882 is \$6,432,100.

out some old ground. Coroner Spencer held his first inquest on the miner's body on Thursday the 15th, and the jury returned a verdict of death from natural causes. A search revealed that the pitiful sum of \$3.85 represented all that remained of the old Argonaut's earnings. And such fortune, such death and such burial, is not an infrequent outcome of the hopes and day-dreams of many California pioneers.—*Mountain Democrat*.

Working Blue and White Cement.

It is a mistake to suppose that all the material which is washed from the gravel mines of this State is of the same character. It is incorrect to assume that the character of the material now being worked in some of the well developed hydraulic mines is the same as it was when the mines were first being opened, and the top strata being removed; when the material was light and easily washed, requiring little or no powder in its disintegration; when the sluices were yet upon heavy grades, and every facility exerted for washing away immense quantities of material. Now, in some of the big mines, properly opened, operations are confined more or less to the bottom stratum, where the gravel is firmly cemented; where immense boulders are constantly met with; where the gravel itself must be blasted again and again before it can be washed into the flume; where in many instances it is carried to the dump a distance of 3,000 or 4,000 feet, practically without disintegration, and where the grade of the flumes have been reduced, of necessity, to a minimum, in order that any outlet at all may be obtained. The great difficulty of working mines of this character is well illustrated by the fact that the Excelsior mine, at Smartsville, although it has a perennial supply of water, can use it, in washing gravel, only 120 days in the year; two thirds of the time being devoted to breaking up lumps of cement and boulders.

A brief description of the character of ground worked by those mines now working the bottom channel or "blue lead" will be of interest. Taking the Excelsior mine, at Smart-

ville, as an illustration, the subjoined is a description by an intelligent and truthful miner of the condition and character of the bank upon which it was operating, when enjoined at the suit of the County of Yuba:

"The gravel and other material in the Smartsville claim is exceeding solid and compact. The bank varies in height from 150 to 200 feet, but will not average more than 175 feet. Of this bank, the first 60 feet above the bed-rock is composed of large boulders (some of which areas much as 20 feet in diameter, and weigh as much as 300 to 400 tons), and of large cobble-stones, weighing from 50 pounds downwards, and of finer gravel, all firmly cemented together by what is known among miners as the "blue cement." Above this is the "white cement," which extends to the surface of the claim, and is composed of a mass of boulders and gravel, firmly cemented together, and which is very hard and compact, and is impervious to the action of water. Drifts cannot be run in in any part of the gravel in said mine without using powder. In running powder drifts in the bank, it sometimes takes three "eight-hour shifts" of miners, working constantly night and day, a week to run 10 feet. When blasted this white cement comes down in immense masses, tons in weight, and it is necessary to blast it over and over again before it is reduced to a size which renders it practicable to wash it through the flume. The large boulders above spoken of, which are found in the lower stratum, are blasted and broken into fragments weighing from 150 pounds to 250 pounds, before they can be washed into and through the flume,

Wyoming Mines.

Miners' Delight District.

A correspondent of the Salt Lake Tribune, writing from Atlantic City, Wyoming, says:

The attention of Colorado capitalists is being called to a section of mining country situated in Miners' Delight mining district, which, for want of time, I failed to mention in my former letter in your paper. A mere mention would fail to give the section above referred to justice, as there is one mine alone which deserves more than passing notice.

For several years past a couple of placer miners, Lovell and Harding, have been working in Strawberry gulch (just where the overland stage road crosses the same, and within a few yards of the old station), with very fair success, having taken out from \$8 to \$20 per day to the hand. Such work could only be done when the spring snows melting, afforded them water. A year ago last summer they washed upon a ledge crossing Strawberry gulch in an east and west direction, and the decomposed rock (barren, as they thought) looked so favorable, they concluded to pan some of the same, which they did with favorable results. They immediately located a quartz vein, calling the same the Bullion. The locators were Harding, Lovell and Nickerson Bros., who immediately commenced sinking a shaft, and the first ten tons of ore taken from the shaft were taken therefrom before the parties had sunk eight feet, and hauled in loose wagon boxes to Miners' Delight mill, a distance of 11 miles. After hauling five times before the ore reached the stamps, it yielded \$505 or \$50.50 per ton. John Hartly, an old Sweetwater prospector, owned a claim adjoining, and fears were entertained that litigation might ensue, when a consolidation was effected whereby Hartly got one-fifth in the Bullion. He sold within a very few days for \$500 to Kuhn, of Ogden, and Newman of Miners' Delight. Harding and Nickerson, Sr., sold last fall fifth each to one Lewis of Denver, for \$1,000 each. Lovell sold last week his fifth to Lewis for \$5,000, the owners at present being Kuhn, Newman, Nickerson, Jr., and Lewis. Lewis erected a 10-stamp mill on the ground, and dropped the stamps about Dec. 20th, having contracted with his co-owners for the delivery of 7,000 tons of ore at the mill, which is situated on the ledge and within a few feet of the discovery. Water in sufficient quantity to run the mill (a steam mill, 40-horse power engine) not being easily obtained, only five stamps have been running, and they only a few hours at a time. The first clean up resulted in \$16 per ton, the second in \$22 and the third in \$29. While water is found within less than five feet of the surface on the ledge, still the same cannot, as yet, be procured in desirable quantities for running the mill steadily. A well has been sunk at the mill 42 feet in depth, which has served to keep the mine dry (the deepest shaft sunk on the ledge being 27 feet). The extreme cold snap of the past month has prevented work being pushed as rapidly as it otherwise would be pushed by the able manager, Mr. Lewis.

Your correspondent visited the mine in November last, and was surprised to see such vast quantities of ore. To say that it is a big thing would not be saying half; it is immense. Prospecting has been done in dozens of places on the claim, and everywhere the ore is uniform in value with that at discovery. It has been stripped on the surface for 100 ft. in width on the ledge with like results. I have seen several pans of dirt taken from the ledge and washed without any pulverizing of the rock; and have seen from \$1.50 to \$7 to the pan, and I have been told that one pan yielded \$25. What must be the feelings of the gold hunters of early days, when they hear of the rich strike on the Strawberry? Many will say, "Why, I passed right over that ground," and ten chances to one, half of them will swear they knew it was there all the time. Yes, you passed right over it within less than a foot of the surface. It has lain for centuries and within 100 ft. of the old Strawberry stage station, where a company of soldiers were for a long time stationed.

The First West Extension of the Bullion is owned by Flike & Miller, and the Second (Midias) and the Third (Dahlonga), extensions west are owned by four Salt Lake parties. The character of the ore is the same as that found in the Bullion, but there has been no development of either of the three properties last mentioned, as they were located at the beginning of the cold weather in November last, and the parties locating had no time to prepare for winter. Prospecting on Strawberry in winter time, means something more comfortable than a linen duster and a wickup.

The First Extension east of the Bullion is owned by the Charles Brother & Co. (Greatrix); the names of these claims I failed to procure. In each of these claims work is being pushed as rapidly as possible, and with the most flattering results. Charles Brothers have an immense body of gold ore, being the exact counterpart of that found in the Bullion. Greatrix has gold in his claim, and, as he says, "nary a wall."

After leaving the two last claims mentioned, and following in an easterly direction what one would guess to be the line of the ledge, and distant from the Bullion about two miles, we come to a claim owned by D. D. Wolf, a close student of Blackstone and a miner of Atlantic. The ore in this claim appears to be different from that found in any of the above mentioned claims, being black slate and iron, and from assays shows from \$90 to \$160 gold per ton. Having a five-foot vein, as Wolf has, if the assays are correct, he has a bigger thing than all

the knowledge he can glean from Blackstone during his natural life will ever yield him.

Adjoining Wolf's claim, which is on what is known as Deep Creek, is the Comet, owned by Salt Lake parties who propose opening up their claims in the spring.

Between the claim owned by Charles Bros. and Deep Creek no indication of mineral is found near the surface. The supposition is, the ledge runs deeper the further we follow it east. This is partly proven when we take a peep into Charles' shaft, as we find he had to sink 20 ft. before he caught the Bullion ledge, while the Bullion owners did not have to sink that many inches.

I know of nothing wanting to make this, in the near future, one of the most prosperous mining camps anywhere in the West, except it be a lack of industry—the kind of industry that should characterize mining men wherever found. There are here, within a radius of 12 miles, seven mills, some steam, some water, with from five to 20 stamps, the owners of which would work ore, or possibly sell. An abundance of timber grows down on us from the base of the Wind River mountains, with splendid roads to haul the same. There is an abundance of water in Rock creek, Willow creek and Sweetwater for running water mills. Hundreds of claims are lying idle, and many others which are being worked could be purchased at reasonable prices.

A town is springing up on Strawberry, and is named Lewiston, in honor of Mr. Lewis, the promoter of the mining enterprise that bids fair to equal any yet seen in the West.

Already we hear inquiries made by Colorado capitalists about the Sweetwater country, and I prophesy that, with the breaking up of winter, will come a rush such as was known here in early days. Let Utah not stand back, but come and see; seeing is convincing.

The Fauna of Arizona.

The fauna of Arizona is imperfectly understood even by our best informed citizens. This is doubtless owing to the immense area of our Territory, and the diversity of climate caused by the varying altitude of the different mountain ranges. The kings of our beasts are the grizzly and brown bear. Fortunately there are but few of these ferocious animals in the Territory. An occasional grizzly may be found in the highest mountain ranges in the northern part of the Territory; but the large brown bear, which in Arizona is about as large as a grizzly, may be found any where in the mountain ranges which reach an elevation of 7,000 feet and upward.

The brown bear of Arizona closely resembles the grizzly; his head is fully as broad as long, but his nose is more pointed, his hair is from four to five inches long, which hangs in tangled knots. During the first month or two after they come out in the spring, they are very ferocious, and if the hunter surprises him or gets in too close proximity he is almost sure to become the attacking party. We know of a number of instances in which prospectors and hunters have been attacked by the brown bear, some of which run very narrow escapes. We ourselves have had an experience with the brown bear which we would not care to repeat.

There are a few cinnamon bear in the northern part of the Territory, but they are seldom found in any of the southern mountain ranges. The little black bear inhabits most of the highest ranges of mountains. Last year they were plentiful in the Santa Catalinas. They are a beautiful little animal, with a coat of fine jet black hair, and are much smaller than the black bear of the north and Western States.

Next to the bear in the cat kind is the mountain lion, which are similar to those found in Colorado and California. They are a very wary but cowardly animal, and will not fight unless they are surprised or pressed. They abound in every part of the Territory and sometimes destroy calves and colts, but are more fond of sheep, of which they eat ravenously. They are the sheep herders' greatest enemy; two adult lions with their young have been known to kill as many as 50 sheep in a single night. Fortunately they are easily poisoned, and they seldom have more than one or two feasts of fresh mutton before they get a dose of strychnine.

The leopard is found on the western slope of the Baboquivaries and the low ranges of mountains to the west, near the Mexican line. He is a more compact built animal than the lion, and full as heavy. The Papago and Yaqui Indians say he is much more to be feared than the lion. He is beautifully marked, and his skin commands a high price, both here and in Sonora, being in demand among the Mexican vaqueros for leggings and saddle trimmings.

The gray wolf inhabits the mountain country, though they are very scarce.

The coyote is found everywhere. He is larger than those east of the Rocky mountains or in northern latitudes.

There are a very few panthers and a few lynx, but wildcats are found everywhere. There are a few wolverines in the northern part of the Territory, but none, so far as we know, have been seen in the south.

Arizona is greatly favored with deer, both of the black and white tail varieties, but their habits are exactly the reverse of the Rocky and Sierra Nevada mountains; there the black tails seek a habitation near the snow line, while the white tails are content to remain in the valleys; here the white tail deer are nearly always found in the higher mountains, while the black tails frequent the foothills and the valleys. The mule deer, which is the largest of the deer kind

in America, is very common on the Colorado river and the low mountain ranges in southern Arizona. They are a closely-built, fine looking animal, and some of them are almost as large as elk. Indeed, we saw one two months ago on the head of the Barbaomari creek, in Pima county, which seemed to us almost as large as the pony we were riding.

Mountain sheep and species of wild goat are found at various points throughout the Territory, though they have been nearly exterminated in many localities by Indians. We have been informed that ibex have been seen in the Santa Rita mountains, but the statement lacks confirmation.

A few elk yet remain in the northern part of Arizona, but there are none in the south that we have heard of.

Pecaries, or musk hog, are very plentiful in the southern part of the Territory. They are small animals of the hog kind, and grow to 60 or 70 lbs. in weight. These are the animals which Goldsmith, in his "Animated Nature," told us rested of nights by hanging their long tusks over the lower limbs of trees, and, thus suspended, sleep securely.

Gray fox are plentiful in all the higher tablelands of Arizona, and in the foothills of the higher ranges of mountains. Beaver are numerous along all the water courses. Of rats we have a number; the common wood rat, the big and little kangaroo rat, and a rat of the wharf species, with a file tail one-fourth longer than its body. Of mice, we have the common house, the kangaroo, the common field, and the little black mouse.

We have the large gray squirrel, the pine squirrel, chipmunk, the common ground, the bushy, striped tail, side striped, the flag tail, the lime tail, and perhaps one or two other varieties.

Of hares we have the black and white tailed jack and the Santa Fe, as it is called in Colorado, but here it is known as "cotton tail." The latter is the common rabbit of Eastern States, but is much smaller here. Our space will not permit of an enumeration of the birds of Arizona, which comprise a very large list. We shall therefore have to pass the feathered songsters; but as many Nimrods outside of the Territory would like to hear of our quail, we will close by stating we are bountifully supplied. We have the mountain and valley quail of the California species; chicken quail and the hawk-billed quail; both of the latter kinds we believe are found only in Arizona in the United States. The hawk-bill is usually known here as the "fool quail," owing to its peculiar way of squatting under cover and remaining there until stepped upon, or poked up with a stick. We also have the "bob white," though smaller than those in the States, with breast feathers of a reddish cast. It is found in the extreme southern part of the Territory between Tucson and Port Lobos on the Gulf of California.—*Arizona Citizen.*

An English Zinc Mine.

A remarkable find of blend at the Magpie mine Derbyshire, is exciting great interest in mining circles in England. The mine is near Bakewell, in High Peak, and has been worked for 300 or 400 years with the exception of a short interval from 1843 to 1869. In the latter year it was again opened out, but the proprietors had a prolonged struggle against water, the great enemy of lead mining in north Derbyshire. For nearly two years, pumping was carried on at an expenditure of 80 tons of coal per week. During this period the owners raised £19,000 worth of ore at a considerable profit; but in consequence of the great expenditure of coal, it was thought advisable to suspend pumping, and to get rid of the water by driving a level. This work was begun in 1873, and was finished in 1881, at a cost of £14,000, the level nearly 2,000 yards long, unwatering the mine to a depth of 196 yards. A few weeks ago Mr. Simmons, the captain of the mine, made the discovery of a seam of blend five feet wide, which increases in width the farther it is explored. Mr. Simmons regards the discovery as most wonderful and altogether unparalleled in England. He estimates that there are at least 50,000 tons of ore in the seam, worth £3 18s. 6d. per ton. The company is now making a road to its rich deposit, and laying down a four-foot track, on which the ore will be conveyed out of the workings. Twenty yards from this find of ore, the workmen came upon an immense natural cavern, 22 yards long, extending for 12 yards overhead and for an unknown depth below water. This cavern was sufficiently large to hold the whole of the debris excavated during six months, and was of great convenience to the company.

LIBERTY, IDAHO.—Bayhorse is having another excitement. The Mill Co. of the Ramshorn lode, located a mill-site near the junction of Bayhorse creek and Salmon River, which is about three miles below the old town of Etna, or Bayhorse. On hearing this fact the excitement grew immense; and the boys went down to the old ranch, known as the Bayhorse Crossing, owned and formerly kept by Frank Wood, and laid out a city and gave it the name of Liberty. Things are said to look lively up there. Fencing lots and making other improvements seems to be the order of the day. We have not been to the new city since its birthday; but intend to do so before it is a year old. Bayhorse can do almost anything, and we see no reason why she cannot build two or three towns. She has material backing, and enough to make them all wealthy locations. This is a warmer location by some degrees than the old town.—*Messenger.*

A Government Asked for Alaska.

Senator Cross has introduced the following concurrent resolution, requesting Congress to pass an Act providing for a civil government for the Territory of Alaska: Whereas, the mining and commercial resources of Alaska Territory are believed to be of great value, and many mining and business companies have been organized in San Francisco and elsewhere for the purpose of developing such resources; and, whereas, the honorable Commissioner of the General Land Office at Washington has decided that no applications for patents for mining lands in Alaska Territory will be received or considered by the Department of the Interior, Congress having failed to organize said Territory into a surveying district; and, whereas, the effect of this decision is to hinder and retard the development of the mineral resources and the settlement and occupation of the public lands in said Territory, and whereas, the said Territory of Alaska is without local government, and its inhabitants have petitioned the Congress of the United States to organize a Territorial Government in said unorganized Territory, and a bill is now pending before Congress with such object in view. Therefore, be it resolved, that the Senate in Congress be instructed and our Representatives be requested to use all honorable means in their power to secure the passage, at the present session of Congress, of an Act of Congress providing for a civil government for the Territory of Alaska.

California Production and Commerce.

The S. F. Journal of Commerce gives the following estimates and records:

Foreign Merchandise—Imports of '82.	\$4,767,968
Merchandise — Exports to Foreign Countries.....	49,625,198
Exports by Rail.....	60,000,000
Gold and Silver Coined by S. F. Mint.....	37,915,000
Precious Metals Produced.....	80,000,000
Lead Product on the Coast.....	8,500,000
Quicksilver Products, flasks.....	50,820
Wheat Crop of California, centals.....	29,500,000
Barley Crop, centals.....	6,000,000
Wool Clip, lbs.....	39,448,349
Value of Tea, Sugar, Rice and Coffee imported in 1882.....	16,233,659
Vintage, gallons.....	10,000,000
Value of Fruit Crop.....	5,000,000
Value of Pacific Coast Mining Industry, 1881.....	98,150,000
Lumber Receipts, feet.....	264,098,814
Population of California, Jan. 1, 1883.....	920,000
Population of Pacific Coast, Jan. 1, '83.....	1,850,000
Population of San Francisco, Jan. 1, 1883.....	280,000
Product Precious Metals on the Coast since 1848.....	2,378,146,186
Receipts of Coal, foreign and domestic, for 21 years.....	9,100,000
Exchanges at Clearing House.....	629,114,119
Inward Foreign Tonnage, 1882.....	1,060,033
Outward Foreign Tonnage, 1882.....	1,123,272
Inward Tonnage, Atlantic ports.....	117,341
Outward Tonnage, Atlantic ports.....	12,026
Steam Tonnage, entered.....	404,948
Steam Tonnage, cleared.....	413,643

Where not otherwise specified, the above figures represent dollars of value.

MINING OUTLOOK IN IDAHO.—The *Ketchikan Keystone* says: The year begins with many assured evidences of the greatest yield yet recorded. Scores of developed mines that have been idle during 1882 are to be worked actively in a very short time, and those that have well-forwarded explorations will be stopped, and thus add largely to the product of 1883. The new properties in every camp, not before known as producers, will swell the list of paying mines, and the placers will show richer returns than for the past half dozen years. It can readily be understood that profits will be larger because most of the mines have their plants of machinery in place, and the arrangements well perfected for steady and increased output. The cost of transportation and reduction of ores is less than has ever been known, and consequently the mineral as mined will bear shipment without the careful sorting into marketable grades once necessary. The close margins upon which ores are now bought, through the establishment of competitive bids, give a higher cash price to the miner than he has hitherto received, and thus everything conspires to stimulate production and encourage prospecting.

TRANSPORTATION CHARGES ON BULLION.—The Boise (Idaho) *Statesman* says: We learn that the U. S. Government has instructed Mr. Wolters, the Superintendent of the U. S. Assay Office, to no longer impose a transportation charge upon bullion deposited at that office for coinage, but to forward the same to San Francisco at the expense of the Government. The result of this order will be to effect a saving to depositors of 1% of the gross value of their deposits, and holders of dust and owners of placers will undoubtedly take advantage of this opportunity to increase their profits and get speedy returns for their bullion.

THE WOOD RIVER TIMES says hundreds of men are arriving every week at Naples, at the junction of the Wood River branch with the Oregon Short Line. Some go to engage in business, others to work on the railroad, while not a few are chronic bums, who drop into town utterly strapped and seeking a country where they may live without working. Some 40 teams and wagons also arrived at Naples and started for the end of the railroad grade toward Boise City. Five hundred additional men and 75 more teams will arrive there in the next two months and go forward with the O. S. L. to Boise valley as rapidly as materials can be delivered to them.

MECHANICAL PROGRESS.

"Steel-Iron."

The question of producing a metal possessing the physical properties of both iron and steel has for some time past received attention at the hands of practical metallurgists and others. One of the latest workers in this direction is Prof. M. Keil, who has succeeded in producing a compound metal which is stated to possess the characteristics of both metals. The Professor, in giving his experiences on the subject, states that the difficulties can only be alleviated when the two materials are intimately united into a whole. After many experiments success has, it is claimed, at last attended them, and a material has been produced answering every requirement, and to which the name of "steel-iron" has been given. The following five descriptions have been made: (1) steel by the side of iron; (2) steel between two layers of iron; (3) iron between two layers of steel; (4) the core of steel, the surrounding shell of iron; (5) the core of iron, the surrounding shell of steel.

This steel-iron is manufactured in the following manner: A cast-iron mould is divided into two parts by a thin sheet of iron securely fixed in it. The fluid steel, as well as the fluid wrought-iron, which have been freed before smelting from substances preventing welding, are poured at the same time, and in the same quantity, into this double mold; the separating plate serving as the medium welding both parts, steel and iron, completely together, so that they form an inseparable whole. The plate serves as a separator and a welding agent at the same time. The success of the operation depends upon the quality and thickness of the plate. The latter must be of a certain thickness, to prevent the two glowing and liquid masses burning through it; and it must not be too thick, so that they are able to bring it up to welding point while rising in the mold. The dimensions of the plates depend upon experience, and are naturally regulated by the dimensions of the castings. The manufacture of the above mentioned five kinds is the same in principle. In Nos. 2 and 3, however, the mold is divided into three equal parts by two strips of plate. In Nos. 4 and 5, the core is formed by a sheet iron pipe standing in the middle of the mold.

It is stated by Prof. Keil that the product thus obtained may be used for a good many purposes. Steel upon iron will be useful for rails, armor-plates and anvils, the hard steel face reducing wear and tear, and also, as in the case of thief proof safes and armor-plates, withstanding the attacks of even the hardest drill while the iron prevents cracking consequent upon heavy blows. Parts of machinery and tools which are subject to powerful pressure, and are exposed at the same time to great vibration are best made of the material with tough core and hard surface. The wear and tear would be slight, while the soft core imparts considerable strength and prevents fractures. From what has been said respecting the quality of this description of steel-iron, it will be seen that the extent of its application promises to be a wide one, partly on account of its undoubted excellence, partly also, from its many qualities, because it may be used for a great variety of manufactures.

Aid of Machinery to Labor.

Labor is a natural burden upon humanity; yet it is the key which unlocks the storehouse of wealth, convenience and luxury. By the use of inventions and applied machinery muscular work is greatly relieved, and results, cheaply and extensively obtained. In all this, however, intelligent skill is not supplanted, but rather there is a wider field created for the same, and more and more does it come into demand as the facilities for production multiply. Man, of course, may exist as our forefathers did, living in a rude and limited way on the necessities of life, and even these secured only at the expense of oppressive toil, but as improvements are made, and varied and enlarged benefits flow therefrom, he rises in the scale of being, and the sphere of life is extended. The easy supply of want in any direction only begets efforts in others, and as matters thus progress, instead of the demand for useful industry being diminished, there is more and more inducement to laborers to employ themselves with the exercise of every faculty.

It is a mistaken view, therefore, to imagine that there is the least tendency in the use of machinery to supersede the necessity of workmen, and take from them all opportunity to labor. Their skillful hands, discerning eyes, and intelligent brains are surely destined to find an ever widening field. Of course, the worker must not remain stationary, content to live and die an antiquated fossil, while all the world about him is changing and progressing. What he once did painfully and slowly with the hands alone he must now more abundantly accomplish through the agency of labor-saving devices and tools. Society has need of more production, and will only be satisfied with even more and more. With its prosperity and progress the laborer shares; and to-day he has more of the comforts and luxuries of life than were enjoyed by kings a hundred years ago. The prejudice against improvement, and the jealousy against capital and associations in their efforts to manage and direct production into more efficient and beneficial channels should disappear. As

changes occur, old ruts should be promptly abandoned. By adapting himself to circumstances as they are thrust upon him, there is not a man who cannot succeed and find a market for his labor far beyond his ability to supply.—*Dubuque Trade Journal.*

Forging a Rudder.

Referring to the forging of a new rudder for the steamer *City of Berlin*, to take the place of one that was carried away in a recent storm, Jas. Johnston, the superintendent of the Patterson (N. J.) Iron Co.'s Works, is reported to have said: "This is the biggest job of the kind we ever had, and there is only one other establishment in this country that would be anxious to get it to do. The shaft is 40 ft. long, the blade is 25 ft long, and the shape of the whole is so irregular that we have to put on counter weights every time it is handled, in order to turn it over under the hammer. It will weigh about nine tons. The blade is made of sheet-iron plates, bolted on each side of the frame. The frame is made of iron, about eight inches square. The open space between the two plates forming the blade is sometimes filled in with resin. This, when melted and poured in, forms the most durable and solid filling. Some, however, use plaster of Paris. Others fill in the space with wood. Finally, others perforate the plates and let water run in. This is probably as good as anything. The frame gives the rudder the desired strength. The plates are only to give a surface. A rudder six feet broad will steer a steamship 400 ft. long."

While the reporter was listening, the building was lighted with the brilliant glow of a red hot box of iron about 15 ft. long and eight inches square, just taken from the furnace. It was, in fact, a part of the outer rim of the curving rudder. In the meantime a corresponding piece projecting from the rudder shaft, which had likewise been heated, was brought from a furnace to be welded on. The two ends that were brought together were like two letter Vs pointing toward each other, thus: \angle \angle . Then several men with great tongs took from the fire two small pieces also shaped like letter Vs, made to fit on the space between the two ends to be welded. These smaller pieces were held in place until a blow or two of the great hammer, giving a 4,000-pound stroke, caused the half melted mass to adhere. Next the whole mass was twisted and turned, and the blows rained faster and harder, until in a few minutes the weld was completed. A similar operation welded the other end of the bow to the post.

"A single false blow," said the superintendent, "might spoil the whole thing. A bit of dirt in it might make a flaw that would cost us thousands of dollars for damages. It takes a good mechanic to boss such a job, and we have to pay him good wages."

"How much do you pay him?"

"We pay that boss hammerman \$12 a day. He is the most important man in the shop."

A SMOKELESS LOCOMOTIVE.—If the item which we copy below be true—that is, if the inventor has really been successful in discovering how smoke may be consumed and used in the employment of an agent for heating railroad cars without the use of stoves—he will be hailed as a public benefactor. The story runs: A locomotive is being built for the Erie railway in which Mr. Mallett's device for consuming smoke is to be tested. In order to give the invention a thorough trial a trip across the continent will be made. There is to be no smoke-stack on this locomotive, and in its place is to be a manhole merely. The air used to condense the steam is employed for heating and ventilating cars, being delivered through a conduit which, with coupling ends, passes along beneath the cars. This system does away with coal stoves or heaters, and supplies the cars with fresh air and warm air without danger of fire in case of a smashup, and also disposes of the cinders.

PAPER OR CAST-IRON FOR CAR-WHEELS.—We gave an item a few weeks since showing the safety of paper as a material for car wheels. Now we have a very satisfactory report on the strength and durability of cast-iron car-wheels, which we find in the report of accidents for November, published by the *Railroad Gazette*. It appears from the report that only three accidents were caused by broken wheels. Two of these occurred on freight trains and one on a passenger train. When we consider, continues the report, that probably more than 90% of all the car-wheels in the United States are cast-iron, and that at least 99% of the freight car-wheels are of this material, it will be seen that the record tells a remarkable story. We are inclined to believe that the proportion of cast-iron to other forms of car-wheels is largely exaggerated in favor of the former in the report referred to.

THE MANUFACTURE OF BESSEMER STEEL.—Official statistics show that the production of Bessemer steel ingots in the United States last year was 1,696,450 tons, being an increase over 1881 of 10%. The quantity of Bessemer steel rails produced in 1882 by the 14 completed works was 1,334,349 tons, an increase of 6% as compared with that of 1881. These figures do not cover rails made from imported steel blooms and open hearth steel rails.

SCIENTIFIC PROGRESS.

Sweeping the Skies.

A correspondent of the *Call*, of this city, writes as follows in regard to the great telescopes which are now in process of construction at Cambridge, Mass.:

A few nights ago I had the pleasure of viewing the heavens through the immense telescope just completed for the Russian government by Messrs. Alvin Clarke & Sons, the same firm who have the contract for furnishing the Lick telescope. The instrument made for the Russian government is the largest yet made. Indeed, the beauties of the celestial system are shown by Mr. Clarke's immense telescope. The instrument now awaits the arrival of Professor Struve, the royal astronomer of Russia, who is expected at Cambridge in a few days. He will test the instrument, and if it proves satisfactory (as it no doubt will) he will ship it at once for home. The glasses alone cost \$25,000. Sir William Herschel would have thrown away his big reflectors in disgust if he could have caught a glimpse of the heavens through this telescope. People who are not familiar with the progress of astronomy have no idea of the work that is being done in the great observatories of the world. With such an instrument as the one the Clarks have just completed, or with the one recently acquired by Princeton College, which lacks but one inch of being two feet in diameter, the geography of the planet Mars is somewhat wonderful. With the new Russian telescope, Saturn, Mars, Jupiter and the other great planets are a revelation to the observer. Saturn, 700 times as large as this globe, suspended in space in the middle of three or four concentric rings, which are nearly 40,000 miles broad, and more than 400,000 in circuit, but less than 100 miles thick, and turned edgewise toward the planet's equator, is indeed an object of wonderful admiration when seen through an immense telescope. They say that Saturn is not inhabited, for the reason that it, with Jupiter and the other large planets, is not yet cooled down and permanently crusted over like the earth. Saturn's atmosphere seemed to be filled with clouds, which presented a most picturesque appearance. Looking at the planet was like taking a station off in space, and watching the earth rotate, only the planet rotates much faster than the earth. Venus is exceedingly beautiful in the telescope, especially during the crescent phase. Work has begun on the Lick telescope, but it will be several years before it is completed.

Man and Animals.

There can be no doubt, says *Nature*, that dogs associate with barking in certain tones special emotional states in their companions. In fact, it is probable that dogs can in this way communicate with each other a wide range of states of feeling. But those states are present states; not past or future. They are their own states; not the states of others.

A dog can call his companions' attention to a worrisome cat, or he may have his own attention roused by the simple exclamation, "cat!" uttered by a human being. But no dog could tell his companion of the successful "worry" he had enjoyed, or suggest that they should go out for a "worry" the next day or evening.

And here we come upon what appears to be a fact which raises man so immeasurably above the level of the brute. The brute has to be contented with the experience he inherits or individually acquires. Man, through language, either spoken or written, profits by the experience of his fellows. Even the most savage tribe has traditions extending back to the father's father, or beyond. And the civilized man—has he not in his libraries the recorded results of many centuries of ever-widening experience and ever-deepening thought?

Thus it is that language has made us men. By means of language, and language alone, has human thought become possible. This it is which has placed so enormous a gap between the mind of a man and the mind of a dog. Through language each human being becomes the inheritor of the accumulated thought and experience of the whole human race. Through language has the higher abstract thought become possible.

ABSORPTION OF HYDROGEN.—It has been shown by W. Hempel that hydrogen is completely absorbed by palladium sponge at 100°, and he has used this as a means of separating hydrogen from a mixture of gases. In order to test the applicability of this property to the estimation of hydrogen evolved in sealed tubes, the author treated zinc with hydrochloric acid in a sealed glass tube containing a palladium spiral. The proportions of acid and zinc were such as to produce a pressure of 25 atmospheres, if no hydrogen were absorbed by the palladium. The absorption was found to be complete. A small portion of the hydrogen had united with the oxygen of the air remaining in the tube. Nearly the calculated amount of hydrogen was obtained from the palladium spiral by heating to 350°. The evolution of the gas was so regular that the author suggests the heating of palladium hydrogen as a means of obtaining chemically pure hydrogen.—*Amer. Chem. Journal.*

How A Man Walks.

One of the most remarkable things about a man's walk is the *diagonal* movement which characterizes it. The reader may imagine the hands and feet to form the four corners of a parallelogram, and the diagonal limbs are, of course, the right arm and left leg, the left arm and right leg. By "diagonal movement" we, therefore, intend to convey the fact that the diagonal limbs during locomotion always swing in the same direction. A soldier on parade keeps his arms motionless by his sides, and on no account must they be allowed to vibrate. This is not what he would naturally do if left to himself. Watch any one person out of the hundreds walking along the streets, and it will be seen that he invariably swings his arms as he goes along, perhaps to an extreme degree if he be a rustic, and less so if town bred. The arms swing by the body like a couple of pendula, and with a speed which entirely depends upon the rate at which he may be walking. The athlete, anxious to complete the given number of "laps" in a mile, or couple of miles, and outstrip his competitors, swings his arms to and fro with a quickness which corresponds with the motion of his swift feet; the business man also swings his arms with a motion which, if not so quick, exactly times with the motion of his legs; and even the idle man about town, lounging along some fashionable quarter, unconsciously gives a slow motion to his arms which corresponds to his tardy legs. Now, if the motion be even carelessly observed, it will be found that the right arm swings forward at the same time as the left leg, and when the right leg is advancing it is the left arm which accompanies it. This is the natural gait, and to convince one's self that it is so, it is only requisite to get a friend to walk across the room in the opposite fashion, *i. e.*, to swing the right arm forward when stepping out with the right leg, and then, in the same manner, when bringing forward the left leg to accompany it with the left arm. Such a gait is both unnatural and uncomfortable to the person who tries it, and also ludicrous to the observer who watches the first attempt of the kind. The diagonal movement of the limbs is the natural method adopted by man when walking, and it is the first and most apparent fact that one ascertains in studying human locomotion.—*Science for All.*

A NEW DANGER.—Two steamers, one the *Lima*, of the Pacific Steam Navigation Co., and the other the United States man-of-war *Alaska*, recently narrowly escaped destruction from falling meteors. Just after sunset on the 12th of December, a meteor plunged into the ocean close by the latter, and exploded with a great noise and a burst of flame just before reaching the water. All on board were terribly frightened. The particulars of the falling of a meteor near the *Lima* are not related. Of course, the danger from such accidents is no greater now than in years gone by; but, the rapidly increasing number of ocean vessels, and the more general spread of information in regard to this, through newspapers, etc., makes such occurrences more noticeable than formerly. A contemporary, in commenting upon this matter, says: "This is not the first time that meteors have fallen near ships, and there is nothing impossible in the suggestion that vessels may have been sunk by them. Meteoric stones have fallen on land which were heavy enough, and endowed with sufficient velocity, to knock a hole through any ship. Within the last 40 years more than 20 vessels have disappeared at sea. How many of them may possibly have been struck and sunk by one of these flying missiles from the sky, some of which follow in flocks in the tracks of comets, while others are lone wanderers in space until they fall within the earth's attraction, and plunge through her atmosphere with planetary speed?"

A THERMOSTAT CURRENT METER.—An ingenious adaptation of M. Breguet's well-known metallic thermometer has been made by M. Dubois, mining engineer. It consists of a fine spiral compound wire of platinum and zinc, suspended in a vertical direction and dipping at its lower end into mercury. Midway there is also a connection between the spiral and a mercury cup inclosing it, formed by two arms branching out from the spiral and dipping into the mercury. The upper half of the spiral is kinked in one direction and the lower half in the other, to prevent changes of atmospheric temperature from altering the zero of the instrument by acting on the Breguet spiral. The current to be measured is sent through the lower half, and heats it by overcoming the resistance of the compound wire. This rise of temperature causes the wire to turn, and, being fitted with an indicator and scale, the deflection of the thermostatic coil is read off.

JUPITER'S SPOT.—The continued change of longitude of the great spot in Jupiter is giving considerable force to the theory that the "spot" is an immense island of semi-cool matter, floating upon a liquid incandescent ocean surrounding the planet.

STUDYING NATURE.—Some one has said that nature has her language, and she is not unvarnished, but we don't know all the intricacies of her syntax just yet, and in a hasty reading we may happen to extract the very opposite of her real meaning.

was in town yesterday. The new works are about completed, and the stamps will be set in motion very soon. The Josephine is undoubtedly one of the best properties in the county.

MARIPOSA.

WHITLOCK'S MINING DISTRICT.—*Mariposa Herald*, Feb. 23: A gentleman who resides in this district, and who is well acquainted with the various mining enterprises in that vicinity, remarked to us a few days ago: "The prospects of the mines look well. The Teats mine is a flattering prospect, and though but little work has been done on it so far, a thorough development is proposed by its owner, Jacob Teats, the coming season. The Buena Vista and O'Gorman mines are both regarded as good prospects. Mr. O'Gorman intends to erect a 10-stamp mill in the spring, upon the Buena Vista mine. The site is graded, and everything is ready as soon as the machinery can be got to the ground. What the people there most need and desire is that capitalists will visit them and make a personal inspection of their mines, as they feel positive that their value can be easily demonstrated to any one who has the necessary capital to be profited thereby."

NEVADA.

THE CHAPMAN MINE.—*Nevada Transcript*, Feb. 23: At the Chapman mine there is about 200 tons of quartz ready for milling. A gentleman who was out that way this week, expresses the opinion that it will pay from \$12 to \$15 a ton. He says that even \$10 ore can be made to pay a good profit in that mine, as the ledges are of good size and easy to extract.

PLACER.

THE IRON WORKS.—*Placer Herald*, Feb. 24: The Iron Company at Hotelling is busy in its preparation for an early resumption of work. The buildings destroyed last September are mostly being replaced. The shed now in process of erection for the storing of coal is large, being 75x200 ft. and 18 ft. in height. They are also erecting a number of cottages which they intend to rent to their workmen. There is also a new structure going up near the furnace which, we understand, is intended as a residence for the Superintendent. The rebuilding of the place and the refitting up of the works is soon to be completed, and great caution has been exercised to prevent, if possible, a recurrence of the late catastrophe.

PLUMAS.

CRESCENT MINE.—*Greenville Bulletin*, Feb. 20: The machinery for the new hoisting works at Crescent mine is well under way at the Greenville Iron Works; water power will be used; the hurdy wheel now so much used being the form in which it will be applied.

INDIAN VALLEY.—The Indian Valley mill was started up by steam power on Monday, and will be kept running in this way until the reservoir is again full enough to permit of a return to water power.

SHASTA.

SOUTH FORK.—*Cor. Shasta Courier*, Feb. 24: A recent visit to the quartz find of Messrs. H. Dunham and J. P. Kingsbury, satisfies me that our incipient "boom" has some solid foundation. Their vein crosses Brincard gulch near Clear Creek. It is of good size and shows an abundance of free gold in the quartz. Messrs. Scott & Schroder have the south extension, which shows considerable rich ore. Messrs. Engle & Rutcheller have the north extension, and report a large ledge of good paying ore. Being somewhat inaccessible to other portions of the district, an adit will probably be built near Clear Creek, using the water of Kanaka. Further search will undoubtedly reveal other paying veins in that vicinity. Messrs. Brown & Zoellner, on Salt Creek, have their adit completed, and are waiting for water. They have a good ledge of fair grade ore. Twenty-five tons are at the adit, taken out in prospecting their ledge. Robinson & Co. have their adit completed, and will get started this week. W. A. Cooper has sold a half interest in his claim to W. Smith. They expect to put up an adit soon. The mines are looking well as usual. The cold weather has prevented the running of adits or mills the past two weeks.

THE BANGHART MINE.—The Banghart mine, four miles from Whiskeytown, and ten from Shasta, consists of a combination of claims, separately marked off to different owners, the entire location extending 3,000 ft. in length. The ledge is located on a mountain at the head of Mad Mule creek, at an altitude of 3,800 ft. and the lead courses north 60° and dips northeast at an angle of 40°. It shows a length of 10,000 yards, and has an average width of 180. The ledge formation is what is here called birds-eye porphyry, and lies between well defined walls of black slate. The principal work on the mine has been performed on the portion belonging to the original discoverer, W. Banghart. Sixteen small tunnels or drifts have been run in along the main vein and sides, aggregating 6,000 ft. in length, and the different upraisers and shafts aggregate a running distance of 3,000 ft. the deepest shaft being 250 ft. In working the mine the gold is principally found next to the slate walls, and the largest deposits at the intersections of multitudinous small veins of quartz, black manganese and oxidized iron, which run almost at right angles across the main vein. The gold extends back from the slate walls into the porphyry, but gradually grows finer in particles as it leaves the slate. The amount taken from this ledge foot up about \$70,000, and most all the work has been done by three men, and the only reduction machinery yet used on the mine is hand mortars and a small horse adit. The largest piece of gold yet taken out weighed 11 pounds, but quite a number of nuggets weighing nearly as much have been found, the beautiful specimen which took first premium at the last great Paris Exposition having been taken from the Banghart.

TRINITY.

THE WORST.—*Trinity Journal*, Feb. 24: The mining season of 1882-3 bids fair to pass into history as the dryest, and consequently the worst, ever experienced in this section. So far it has amounted to simply nothing.

TUOLUMNE.

TABLE MOUNTAIN BOOM.—*Tuolumne Independent*, Feb. 24: Since our last, miners in Table Mountain for miles in extent are developing their different properties with good results:

A. S. F. Co. which has purchased the Rough and Ready, is working the ground with hydraulic, and a good clean-up is expected. The claim is looked upon by miners generally as a drift claim.

The Montezuma Co. have re-timbered their tunnel entire 1400 feet, to the bed-rock on the opposite shore—exposing a bed of gravel over 300 feet wide, which averages very fair—in some places getting large prospects. The contractors have been engaged since June last in putting the mine in order, and will now commence to drift up and down the channel. This is a large property, and fortunes enough in it for a great many people.

The Boston claim is one that was worked years ago. Mr. Morris & Co. has been engaged for some time past in opening new ground, and was to have commenced last Monday taking out gravel.

The Empire, owned by Gen. A. J. Hatch & Co., of Nevada, have not fairly got to work as is their intention. The last account is that the gravel is paying about \$17 per day to the man.

Messrs. Beynau & Sons, in the old New York channel, have sunk a new incline for virgin ground. In early days this claim paid large sums to the owners, but a lawsuit on this same ground, in which Gen. Darrow and others were interested, closed down the works, and the claim has laid idle ever since. The Beynau's knew the ground, and have run a new incline—the old tunnel not being in a condition to work through. Last week, in a small drift, they took out 14 ozs. of washed gold, and there is plenty more left of the same sort. For a long time prior to this Mr. Beynau had been endeavoring to associate some one with him to help work the property for half the claim. He has now accomplished the object in his own family, and the mine is not now for sale.

GOLD CLIFF.—*Mountain Echo*, Feb. 21: Quite a number of men are at present employed in the Gold Cliff, and the mine has every appearance of being one of the richest discovered in this section for many years. Thirty stamps are kept daily pounding, and we understand that more are soon to be added.

Nevada.

WASHOE DISTRICT.

UNION CONSOLIDATED.—The joint Sierra Nevada east crosscut on the 2900 level is now in vein porphyry of a more solid character. It shows few seams of clay or quartz. The joint Mexican east crosscut on the 2900 level is making the usual progress, and is still in favorable ground. The new pumps at the Union shaft were started up on Thursday of last week, and are working well and smoothly.

SIERRA NEVADA.—The east crosscut on the 2700 level still continues in the cross course of cross vein. This vein has clay walls of considerable thickness. The north and south vein will probably soon be reached.

NORTH GOULD AND CURRY.—The shaft is cutting some quartz of a good appearance, and which seems to be increasing in quantity as work progresses.

HALE AND NORCROSS.—The north drift on the 2600 level, joint with Savage, is making good progress in vein porphyry. No prospecting will be done until the drift reaches the Savage south line.

OPHIR.—The station in the joint Mexican winze is completed, and the guides are all in place for the second line of hoisting cages.

MEXICAN.—The work of putting guides into the second hoisting compartment of the joint Ophir winze from the 2900 down to the 3100 level is completed.

CROWN POINT.—The old upper levels continue to yield about the usual amount of low-grade ore. Some prospecting for new deposits is now being done at various points and occasional bunches of ore of low grade are being found.

UTAH.—The west crosscut on the 1350 level is making good headway in a favorable formation, consisting of quartz, clay and porphyry. This crosscut will be continued until the west wall is found.

SAVAGE.—The north drift on the 2600 level, joint with Hale and Norcross, is making good headway, and is in a favorable formation.

POTOSI.—The main south drift on the 2600 level is making over 60 feet per week. The ground is a mixture of quartz, clay and porphyry of a favorable appearance.

ANDES.—The west drift is still in a mixture of quartz and porphyry of a promising character.

CALIFORNIA.—On the 2900 level the main south drift is being advanced at the rate of about 20 feet per week.

YELLOW JACKET.—Are shipping about 70 tons of ore per day. A considerable amount of prospecting is being done at various points, and more or less low-grade ore is being found.

ALTA.—Good progress is making in the drain drift which is to connect with the south branch of the Suro tunnel. The ground continues to blast out very well.

GOULD AND CURRY.—The west crosscut on the 2500 level is making rapid progress in vein porphyry, with occasional small seams of clay and quartz.

UNION SHAFT.—New pumps working well and smoothly. The hoisting of men and rock has been fully resumed.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, Feb. 24: The crosscut from the drift, at the bottom of the main winze from the fifth shaft level, has been extended 14 feet, its total length being 28 feet. It is still showing spots of rich sulphurets in the face. Crosscut No. 2, on the same level, has been advanced 11 feet without developing any change in the formation. A small quantity of excellent ore is being extracted from the stope above the fourth shaft level. The stope above the first shaft level continue to look promising, showing no diminution either in quantity or quality of the production of ore. There are no changes of note on the other shaft levels. The adit and levels above present the usual appearance. The stope above the ninth and tenth levels are holding their own remarkably well. The ore body in the winze, at the eastern end of the ninth level, has given out entirely, but sinking still continues with the expectation of its coming in again. Everything is running smoothly at the hoisting works, and all work in the mine is progressing in a satisfactory manner. Mill No. 2 is running steadily, and doing good work. Five of its stamps are employed in crushing a lot of 120 tons of fine ore from the Great Western mine, in Garfield district. For this reason only about 50 tons of ore, are being delivered daily from the company's mine, that being the full amount required to run the mill. The weekly shipments amounted to \$26,558.64 for the week ending February 22d, and aggregate \$58,974.79 on February account to the same date.

MOUNT DIABLO.—The stope above winzes No. 1 and 2, shows some \$65 ore that looks encouraging for opening. A body of \$75 ore, 2 feet in width, has been developed in winze No. 2. The intermediate drift, below the third level, and west of winze No. 4, shows a 4-ft ledge of \$50 ore, that is somewhat mixed with waste. The intermediate stope above winze No. 4, has opened several inches of ore assaying \$100, and is promising further developments. A small amount of \$150 chloride is being stoped from winze No. 1, between the second and third levels. Some eighteen inches of \$80 ore have been encountered in the west drift from the Callison winze. Considerable \$70 ore is being stoped from various places in the intermediate, below the first level.

TUSCARORA DISTRICT.

NORTH BELLE ISLE.—*Times-Review*, Feb. 23: Good progress has been made with the work at the station on the 300 level. Will be ready in a few days to commence crosscutting.

ARGENTA. South crosscut from winze is in 25 feet. Have commenced sinking below the drift, and this morning there is over two feet of rich ore in bottom of the winze.

GRAND PRIZE.—The north crosscut on the 700 level is in 137 feet, and has cut through a ledge showing some low grade ore—the quartz is very favorable looking. Have started a drift west on the ledge. Everything working well, and fuel continues to come in quite freely.

NAVAJO.—Since last report work has been resumed in the shaft, and as there will be no water to handle we will make good progress in sinking. Drift south, on 450 level has been extended 11 feet. The vein shows a little better width, carrying the usual grade of ore. Drift south, on the lateral vein, 350 level, has been advanced 15 feet; total length 107 feet. Stope throughout the mine are looking well, and yielding the usual grade of ore. Everything running smoothly at mine and mill.

WHITE PINE DISTRICT.

HAMILTON MINING PROSPECTS.—*White Pine News*, Feb. 24: Advice from Hamilton inform us that bodies of good ore are being developed in the Rescue, Stafford and Original Hidden Treasure mines at that place, which are the property of the Sweetwater Company. The Eberhardt tunnel is also said to be looking well.

Arizona.

A VERITABLE BONANZA.—*Alta Arizona*, Feb. 17: The Hackberry mine, owned by John Howell and others, is one of the best on the Pacific slope. Our present sheriff, Robert Steen, a mining man of sound judgment, told the writer over a year ago that he was familiar with all the great mines of Nevada and many of the mines of Arizona, and that he considered the Hackberry the best mine he ever saw. Recent developments of the Hackberry go far toward substantiating Mr. Steen's high estimate. This mine is situated something over a mile from the town of the same name and only about two and a half or three miles from the A. & P. railroad. It has an incline shaft of some 550 ft. in depth, probably the deepest shaft in the county, with two levels. At a depth of 270 ft we come to the first level having a drift running north and south of over 200 ft each way on the ledge. Work has been prosecuted with unabated vigor on the mine for over a year and some weeks ago a large body of ore, assaying over \$700 per ton, was encountered. Since coming upon this rich ore body, enough work has been done on it to prove beyond a doubt that it is a veritable bonanza. The second level is 400 ft from the surface and will soon be connected with the one above by a winze. The re-stamp mill at Hackberry will soon start up and then will be inaugurated an era of prosperous times at that place, the beneficial effects of which will be felt in every part of Mohave county. It is most fortunate that this rich strike in this deepest of Mohave county's mines occurs just as the railroad is coming to our relief. Situated as the camp is, the first to greet the eye of the capitalist or prospector coming from Albuquerque on the cars, its prosperity now fully assured, will be of incalculable benefit to the entire community.

SILVER DISTRICT NOTES.—*Arizona Sentinel*, Feb. 24: The Felicity mine of Silver district, owned by Capt. MacLeod and associates, is a good prospect and the active development of the mine will be commenced at once.

The Black Rock mine is turning out lots of good ore. A contract has been let to our old friend Mr. Juan Noriega to haul the metal to the smelter at Norton's Landing.

The Nevada mine is being worked by Dr. Stanley, and the quantity of metal taken is very encouraging.

The probabilities are that by the middle of April the Black Rock smelter will commence operations. The masons are now on the ground erecting a brick building and all the machinery and material is on hand to complete the works. This enterprise when fully under way will prove of great benefit to Silver district, as the company will purchase at liberal figures for cash all smelting ore offered them.

The Clip mill is rapidly approaching completion, and with its success will inaugurate a new era in the mining industry of this county. There are a large number of mines in this section that do not produce ore of sufficient value to ship, but which without doubt would pay handsomely to mill on the ground.

A custom mill to-day, in Silver district, would be a grandest factor in the success of that camp.

The Miners of Silver all wear smiling faces, and are happy, for at last they have every reason to believe that the camp is about to enjoy a lively and permanent boom.

Colorado.

THE JAMESTOWN EXCITEMENT.—*Georgetown Courier*, Feb. 24: A number of Georgetowners left for Jamestown yesterday. Mr. Hilderbrand made several assays of the ore from that district, which ran from \$35 to \$62 per ton. The dumps of many of the mines about Georgetown will run as well. Last week 8 tons of dump material from the Fred Rogers mine was milled, which returned \$44 per ton. The Moline tunnel has 7 ft of ore, carrying from 25 to 30 ounces of silver to the ton, and from 50 to 65 per cent of lead, and there are numberless mines in this vicinity carrying like bodies of ore, but can not be profitably worked on account of the extortionate charges of the Colorado Central railroad for transportation.

DUMONT.—Bids are being received for a contract to be let upon the Ohio shaft for 100 ft of sinking. An engine is to be erected shortly. The Albro never

presented a more promising appearance than at present, and also the Rosa. The Hancock property of the Clear Creek Co., upon which an adit is being driven, and which is in 70 ft, presents a very promising appearance. The Mansfield mill has started up, and will treat the free-milling ore from the Albro.

Idaho.

RICH STRIKE ON EAST FORK.—*Wood River News-Miner*, Feb. 17: We have frequently referred, during the past few months, to developments in progress on the Chloride mine, in the Gorman district on East Fork of Salmon, and mention has been particularly made of the fact that a tunnel was driving to intersect the vein at a good depth. The Chloride has, from the grass roots, always been a paying property, and the belief has been general among mining men that it bore indications of coming to the front as the leading mine of the district. This belief is now confirmed by developments made last week in the tunnel mentioned. Mr. Ole Rorem, superintendent of and interested in the Chloride, arrived Wednesday from the mine and states that the tunnel, which has been driven in 172 ft, tapped the vein at a depth of 130 ft, last week. The vein at the point of intersection has an exceedingly well defined vein of ore 6 ft in width. The character of this ore is antimonial silver and chlorides, and assays from \$600 to \$1,000 per ton, which is a marked increase in value over that taken from the surface. The surface rock, of which there are 600 sacks on the dump, mills from \$350 to \$500 per ton. The discovery of such a vein of ore at the depth of 130 ft, taken in conjunction with the flattering showing above ground, certainly places the Chloride in the first rank for permanency and intrinsic value, with the other properties of the district. Nor is the discovery referred to above all, Mr. Rorem, while running a cut on the surface, recently, encountered a body of galena about 40 ft up the hill from the main ledge, and from appearances it is a "breakover" from a 3 or 4 ft galena vein which he expects to find firmly "in place" with a little more work. Four men have been constantly employed for several months and will be continued in pushing drifts on the antimonial and chloride vein already cut, and in opening up the galena vein. The Chloride is situated 12 miles from Sawtooth and 8 miles from Galena, and is surrounded by properties which have been worked to a handsome profit for several years. It is of easy access; timber abundant and milling facilities numerous.

SMOKY MINING DISTRICT.—*Bellevue Chronicle*, Feb. 20: This promising camp is situated about 30 miles west of Bellevue, and is to all appearances a continuation of the great mineral belt on which are situated the Minnie Moore, Star, Bullion, and a number of the Deer Creek mines. Several claims in this new district have been sufficiently developed during the past season to insure them to be permanent and paying mines. The ores are of various kinds, consisting of carbonates, galena, gray copper, native silver, black sulphurets and zinc blend, and are generally of a class known as high grade, some of the ores assaying well in both gold and silver. One of the grand features of this camp is its extensive placer mines, which will doubtless be vigorously worked during the next summer and for many years to come.

New Mexico.

WILL START UP.—*Hillsboro Prospector*, Feb. 21: The new machinery is being put in order and in a few days the mill will start up. The company intend to light up with electricity and add new improvements from time to time. With the starting of the stamp mill and taking out and shipment of ore from the Paul Jones and Tellurium, by Mr. Dennis Findley, and the force put at work on the Copper King, all combined will give Hillsboro a start toward a business boom, and the output will certainly boom the reputation of our camp.

Oregon.

NOTES.—*Jacksonville Times*, Feb. 23: The head of the Sterling ditch is thawing out and piping is about to commence.

The prospects do not seem favorable for an extended run for many of the miners.

Dale & Son, who are mining below the Eagle flouring mill, have found new gravel beds that prove remunerative.

N. Cook, of Willow Spring, informs us that miners are at work in that vicinity and are able to do several hours work daily.

Klippel & Keaton, of Poorman's creek, are able to work 8 hours out of 24 by catching the water in their reservoir.

J. T. Layton, of Applegate, is hiring quite a force of men to clean out his long line of ditch, which work will take some time. He has not done much so far, but expects to make a good run yet.

The melting snow has enabled many to work their claim. There is an unusual quantity of snow in the mountains and those whose ditches head there will have an ample supply of water for a while.

Ross & Co., have purchased C. H. Barkdell's title to the quartz ledge in Blackwell district, which paid so well about two years ago, when \$600 was pounded out with a mortar in a short time. Prospecting will be commenced at once.

Most of the miners are busy at work since the pleasant weather began, but unless rain begins to fall soon, there will be a dearth of water. Those who rely on gulches and short creeks are not liable to do much this season, without the spring is late and wet.

Utah.

A REVIEW.—*Salt Lake Tribune*, Feb. 24: The week has been a quiet one in mining circles. The receipts of bullion for the week were \$706,870.47, against \$167,729.59 the preceding week. The shipments of metals from this city for the week ending Feb. 17, comprised 46 cars of bullion, 1,147,024 lbs; 5 cars copper matte, 103,000 lbs; 1 car bullion, 21,225 lbs, and 1 car refined lead, 24,160 lbs; making a grand total of 53 cars, aggregating 1,295,409 lbs. The shipments of the Horn Silver for the week are 24 cars, valued at \$72,000; previously reported for the current calendar year, \$466,500; total \$538,500. The Ontario shipments for the week are 4 bars valued at \$3,475.63; Frisco mine, 3 cars, valued at \$6,439.45; Silver Reef, two bars, valued at \$3,230. Bullionville shows shipments of 1 car, valued at \$1,467.69.

How to Foretell Frost.

EDITORS PRESS:—In a pamphlet published under the above title by the Signal Service Bureau, I find some statements which are liable to do a great deal of harm if acted upon. As these statements are put forward with the authority of the Signal Service Bureau, and as to find out their inaccuracy would require the investment of seven dollars in the purchase of a dry and wet bulb thermometer, it is better that their inaccuracy should be pointed out.

The principle involved in foretelling frost, as set forth in the pamphlet in the ascertainment of the dew point, it says:

"The ascertainment of the dew point is of great practical importance, particularly to horticulturists, since it shows the point near which the descent of the temperature of the air during the night will be arrested. For when the air has been cooled down by radiation to this point, dew is deposited, and latent heat is given out. The amount of heat thus set free being great, the temperature of the surrounding air is immediately raised. The same process continues to be repeated, and thus the temperature of the air in contact with plants and other radiating surfaces may be considered as gently oscillating about the dew point. If it rises higher the loss of heat by radiation speedily lowers it. Thus the dew point determines the minimum temperature of the surface of leaves on the ground during the night."

This quotation contains the gist of the pamphlet. Find the dew point before retiring for the night, and then you know how low the thermometer will fall and whether a frost is to be expected before morning. A few figures from the meteorological journal which has been kept for the last few years at my sanitarium on St. Helena mountain, will suffice to show the inaccuracy of this statement. I will merely quote from my journal the records at the time of our earliest and latest frosts, although it contains many more striking instances of the fallacy of the law.

Date.	Hour.	Dry.	Wet.	Dew point.	Therm. on grass.	Remarks.
1878.						
April 19.	9 P. M.	39°	38°	30°	20°	Sharp frost, potatoes cut down.
May 28.	9 P. M.	42°	40°	33°	20°	Beans killed, corn cut off.
Oct. 12.	9 P. M.	45°	43°	40°	25°	Sharp frost.
1879.						
May 14.	9 P. M.	43°	41°	30°	28°	Heavy frost, killed beans, tomatoes.
May 21.	9 P. M.	45°	44°	42°	30°	Frost.
Nov. 9.	9 P. M.	37°	36°	35°	29°	Heavy frost.

These figures suffice to show that with a dew point at 38°, or even 42, at night, damaging frosts may occur before morning, and the temperature, instead of oscillating about the dew point, generally descends many degrees below it. From a table of observations which, by a most extraordinary infatuation, has been published in Lient. Allen's pamphlet as illustrating the application of the law of oscillation about the dew point, I will cite a few figures which furnish the strongest evidence that could be adduced against it:

	Dew point at 11 P. M.	Min'm during the night.
Campo, Cal.	6°	32.2
Fort Verde, Arizona.	36°	31.9
Pioche, Nevada.	9°	32
Fort Grant Arizona, Nov. 2.	36°	32
" " " " 3.	18°	32
" " " " 10.	39°	32
" " " " 24.	19°	32
" " " " 26.	20°	32
Fort Gibson, Nov. 27.	36.2°	32.5
Prescott, Arizona, Nov. 29.	43°	32

Here we have instances of the dew point varying from 5° to 43°, or a difference of 38°, and the minimum temperature during the corresponding nights not varying more in any one instance than 0.6 of a degree. In the Fort Grant observations, we find the dew point at 11 P. M. varying from 15° to 35°, and yet in every instance the minimum temperature reached during the night is exactly the same, or 32°, a pretty example of the manner in which the minimum temperature oscillates about the dew point.

The fact is, nearly the whole of the pamphlet is a barefaced plagiarism from Buchanan's introductory text-book of meteorology, published in England in 1871. In that country, owing to the atmosphere being generally nearly saturated with vapors the indications of the wet bulb in connection with frost have a certain importance, as when a portion of the vapor is deposited as dew there is an unlimited supply to continue the precipitation and thus keep up the temperature. Besides this, the large amount of vapor in the air diminishes radiation so that the night temperature does not fall so readily. A full discussion, however, of the climatic differences between the two countries as they affect the indications of the dew-point would lead me too far at present. It is an interesting question, and I hope to find time to ventilate it before long.

From observations recorded in my journal, and from the figures contained in Lieut. Allen's pamphlet (the correctness of which I have very much doubt) it is evident that the minimum original temperature instead of oscillating about the dew-point, sometimes falls 17° below it, and at other times remains 24° above it, thus rendering the evening dew-point a very fallacious guide for indicating frosts.

JAMES BLAKE, MD.

San Francisco, Feb. 9, 1883.

The Mines and Census.

The second edition of the compendium of the census will be published in a few days. From advance sheets it appears that the total production of gold for the census year was \$33,609,663, and of silver \$47,170,957. The report states that, in addition to the returns received directly from the miners, there are several minor points to be included in the total yield. A larger item than it is usually considered to be is the annual handling of rich specimens. This is not accounted for in the mine productions as reported, while it is impossible to state the actual amount absorbed with any degree of precision. A careful estimate would place the value of gold nuggets and ore annually added to the cabinets of collections at not less than \$150,000, and that of silver at about \$50,000.

This, in view of a great number of mineral collections maintained throughout the mining territory, is certainly not an overestimate. There is quite an extensive manufacture of gold quartz into jewelry and souvenirs, particularly in San Francisco. The value of the gold so ab-

gold yield and less than three per cent. of the silver. A similar divergence is observed in other portions of the mining region, the two precious metals occurring side by side, but often in widely disproportionate quantities.

Diaspinae.

We give on this page a handsome engraving of two species of scale insects belonging to the genus *Diaspis*, and one of another genus which is closely allied thereto. The engraving is from Prof. J. H. Comstock's Report to the Department of Agriculture, in which his investigation of California insects is recorded. Fig. 1 is the "rose scale" (*Diaspis rose*), which may be found in many gardens in our State, and in other States. Fig. 1 shows the way the insects mass themselves upon the twigs of the rose. Fig. 1 a is the female scale insect, and Fig. 1 b is the male scale, both enlarged. This insect is a grievous pest to the raspberry and blackberry plants, and must be exterminated to ensure

SCALE INSECTS INFESTING THE ROSE, THE JUNIPER AND THE EUONYMUS.

sorbed probably does not fall short of \$5,000 annually. In 1870 the United States Mining Commissioner estimated the amount of gold hoarded as specimens or worked up by local jewelers at \$40,000. The same authority estimated the annual loss of gold dust in handling as currency at \$100,000, but the practice of using dust for money has almost disappeared, and the amount so lost is now very small. Another indefinite quantity is the value of the precious metal lost in melting, assaying, etc.

A study of the relation of production to population develops some curious figures, ranging from an average of one mill per capita in Nevada, the intervening series indicating, with great precision, to what extent mining is a factor of wealth. In several localities the product per square mile varies from one cent, in the case of Alaska, to \$18,520 in that of Colorado, the intermediate average forming another standard of developed mineral resources, so far as the precious metals are concerned, from a different point of view, roughly corresponding to that of the relation of production to population.

The leading mining States are Colorado, California and Nevada, followed by the Territories of Utah, Montana, Dakota, Arizona and Idaho, in the order named. The proportionate amounts of gold and silver furnished by each vary greatly. Thus, while Colorado furnishes 40% of all the silver in the United States, it yielded but eight per cent. of the gold. California, on the other hand, is the source of over half the

good growth and fruiting. It is destroyed by spraying with a solution of concentrated lye, half a pound to a gallon of water, or by other effective insecticidal solutions.

Fig. 2 is the juniper scale (*Diaspis Carulei*), which is found abundantly on the junipers' and arbor vitae at the East, and Fig. 3 is another closely allied insect infesting the euonymus, which, because of the oblong form of its scale, is placed in the genus *Chionaspis*, and is named *Chionaspis euonymi*. This insect infests the euonymus in the Eastern States, but at the south and at Havana is found upon orange trees.

PLANT EVAPORATION.—The amount of water which passes through the roots of a plant is something enormous. Dr. Laws, of England, has proven that an average of 2,000 lbs. of water is absorbed by a plant for every single pound of mineral matter assimilated by it. It has been shown at the French Agricultural Observatory, at Montsouris, that 7,02 lbs. of water pass through the roots of a wheat crop for every 104 lbs. of grain produced. These 727 lbs. of water are required to produce one pound of grain. It is also found that more water is needed on poor soil than on rich. Good, rich soil will produce a pound of good grain by the absorption of 727 lbs. of water, while very poor soil requires 2,700 lbs. of water to give a pound of very poor grain.

Genesis of Metalliferous Veins.

At the last meeting of the Academy of Sciences, held on Monday evening, Prof. Joseph Le Conte, of the University of California, read a very interesting paper on "The Genesis of Metalliferous Veins." We have space for a brief extract only: "The phenomena of metalliferous deposits by saltiferous action at Sulphur Bank, California, and Steamboat Springs, Nevada, had tended to confirm what he had previously believed to be the most probable theory of vein formation. The structure, mode of occurrence and contents of these veins no longer leave any room to doubt that they have been formed by deposit from solutions. If any doubts still linger in any mind on this subject, they are now dissipated by the phenomena of deposit, still in progress at Sulphur Bank and Steamboat Springs. The question is now settled forever that metalliferous veins are deposited from liquid forms. He is satisfied that the old theory of sublimation must now be abandoned, and minutely described the process of deposit from solution, constantly going on at Sulphur Banks, through the agency of up-coming solfataric waters, when recently liberated from greater pressure and super-heated conditions. When such solutions approach the cooler surface of earth's crust, they are relieved and enabled to precipitate metallic substances along their lines of percolation, or in fissures, forming veins. In studying the conditions of deposit we must bear in mind that the magnificent chemistry of nature is far more subtle and refined than that of the best appointed human laboratory; and substances which are regarded as practically insoluble by man, cannot be so regarded in the great laboratory of nature.

The infinite patience of nature and the infinite slowness of her operations, must be taken into account. In the perpetual circulation of subterranean waters, infinitesimal deposits continued and accumulated through almost infinite time, producing large results. Thus mineral veins may be composed of substances of extreme insolubility and yet be deposited from solutions. In fact such extreme insolubility, or at least very feeble solubility, appears to be a condition of mineral vein formations, for otherwise the minerals would in most cases be brought to the surface, instead of being deposited below. Solubility is notably increased by heat, especially super-heat, and by pressure. This beautifully illustrates the law of correlation and conservation of natural forces, furnishing an example of the equivalency of mechanical and molecular forces. There can be no doubt that the solvent power of water may be increased, without apparent limit, by a corresponding increase of heat and pressure. Hence waters deep in the interior of the earth, especially in volcanic regions, where they are under heavy pressure and super-heat, have their solvent power greatly increased. Such waters coming up slowly toward the surface through fissures, would have their solvent power diminished both by cooling and by relief from pressure, and must of necessity deposit in their courses, and thus form mineral veins.

The Commonest Forms of Metallic Ore

Are metallic sulphides. The solubility of silica in alkaline carbonates is well known. He spoke of organic matter as a universal reducing substance, with which all these solutions came more or less in contact. Hot solfataric waters, circulating at great depths, are necessarily under heavy pressure, and we know they contain alkaline carbonates and alkaline sulphides and will take up silica, earthy and metallic carbonates and metallic sulphides, which they will deposit, partly by cooling and partly by relief from pressure and heat, as they come slowly toward the surface and thus form metalliferous veins. Chemical reactions also facilitate the process. The more we study the chemistry of nature the more we are impressed with the importance of organic matter as a universal reducing agent. It is quite probable that organic matter circulated in the same solution with metallic sulphates and was a frequent means of reducing these and depositing them as metallic sulphides. There seems to be a reaction at the California Geysers, where a black, inky deposit of iron sulphide is produced by the action of alkaline sulphide on iron sulphates. Had this reaction taken place sufficiently slowly, the sulphide might have been crystalline. All these methods, and perhaps many others not yet imagined, may occur, but the first, viz., by cooling and relief from pressure, is probably of most universal occurrence.

He believed many subterranean waters to be in that very slow condition of movement most favorable to the deposit of minerals in fissures, where the leaching process proceeds, contributing something from the wall rocks, but the main supply of metallic substance comes mainly from the depths, under conditions of pressure and super-heat. Nearly all circulating fluids terminate their movements on the surface. Metalliferous veins are formed by saltiferous action, which has been preceded by volcanic action. He alluded to the copper and silver-bearing sandstones of Utah. Sedimentary rocks derive their mass from the disintegration of igneous rocks, hence the marvelous variations in vein constituents. Few metallic deposits are richer at greatest depths. The crust of the earth in common with all material things is constantly progressing along a perpetual cycle of changes. He spoke of gold veins as the most difficult to account for, but explained clearly their methods of deposit in full accord with the rules here laid down. In solfataric springs he claims that nature's process of vein deposits is clearly revealed, and their study is invaluable.

THE ENGINEER.

American Steamboats Sweep the World.

There is apparently a large and extended market for American flat river steamers on the shallow navigable rivers of Europe and Asia. In China they have already effected almost a revolution in the water-carrying trade of that empire, and we hear that there is a brisk demand for them already on the Volga. The plan adopted in that case by the American builders is to take out the machinery with them, and to build the steamers of timber on the spot. This plan produces a steamer much cheaper than the iron river steamers exported from England, which have been in use there for some time. Not only is their success due to that cause, but more especially owing to the fact that the American built boats only require a draft of four feet, while most of the English steamers require nine feet. Even a draft of five feet bars the navigation through a great portion of the river, and the speed of the wooden American boats is said to be better than that of any of their iron competitors. The light draft of the American boats has opened up a navigable length of some 2,000 to 2,300 miles on the Volga, which will probably induce considerable further orders for the other large rivers of Russia. There should be an equally good market for such steamers on the rivers of the Argentine Republic, which are very wide, but for the most part shallow. We understand, however, that there is a strong prejudice against them, owing to their liability to catch fire—the first two which were run on the Plate having been destroyed by fire. We do not see why America should have a monopoly of such flat-bottomed river steamers, and we recommend this to the attention of English ship builders, though, as a nation, we are said to be the last to suit our goods to customers' requirements. —*Marine Engineer.*

A REMARKABLE RECORD FOR SAFETY.—It is very easy to make an assertion, but it is not always easy to prove it. This, however, is not the case in the present instance. When it is said that the New York, Penn. & Ohio railroad has a record for safety possessed by few, if any, railroads in the country, the assertion is not made as an idle boast, but can be borne out by substantial proofs. But one passenger has been killed in the history of the road, and that was through no fault of the company. It was caused entirely by the person's own carelessness. With this exception not a single other passenger has been killed or seriously injured. This certainly is a remarkable showing when it is considered that it covers a period of 22 years, and is exhibited by a road that forms a part of one of the great trunk lines between the East and the West, over which a large volume of travel is constantly flowing. This record has not been the result of accident; it has been brought about through the utmost care in every department connected with the construction and operating of the road. The building, keeping up and equipment of the road has always, during the 22 years of its existence, been first rate in every particular. Equal attention has also been paid to the personnel. None but the most competent men are put forward as officers and managers, or engaged as employees. Eternal vigilance has been the price of safety, and it has paid in dollars and cents as well as in the saving of life and limb.

RAILROAD BUSINESS.—There are now 115,000 miles of railway in the United States, which, reduced to fair values and excluding "watered stocks" have cost, with the equipment, more than \$5,000,000,000. This sum is more than one-tenth of the value of the whole property of the people of the United States, including private lands, and more than one-fifth of the whole capital which the products of labor have placed upon the land. In 1881 the railroad employed in operating the roads and in construction 1,600,000 persons, equal to a seventh part of the male adult population of the United States. In the same year they paid out \$450,000,000 for wages and material. These figures show the very great relative importance of railway property in this country, and the vast demand for labor which its service creates. In 1881 the railroads of the United States moved 350,000,000 tons of freight. Of this tonnage more than nine-tenths was made up of food, fuel, and materials for shelter, commodities in which the working people—using that term to distinguish the great body of the people from capitalists, as a class—have a common and equal interest as consumers.

AMERICAN RAILROAD SYSTEM FOR JAPAN.—Recent advices from Japan report that the intention of the Japanese Colonization Department is to adopt the American system of railroad building in the extension of the railroad system in the northern part of the Empire. This decision is attributed to the economical and satisfactory working of the railroad from Sapporo to the sea coast in Yesso. This road was built by Col. J. A. Crawford.

USEFUL INFORMATION.

Spotting of Looking-Glasses.

A trouble of this kind is frequently met with by housekeepers. It is generally caused by undue exposure of the glass to the sunlight, or to the heat of a stove or fire-place. It is not as generally known as it should be, says the *Manufacturer and Builder*, that the amalgam with which looking-glasses are coated, to give them their perfect reflecting property, is very readily crystallized, when exposed even for a short time to direct sunlight, or to strong heat from a stove or fire-place. A mirror, hung where the sun can shine out, is soon spoiled from this cause, taking on a granulated appearance, which is familiar to most housekeepers. Where this action is allowed to proceed for some time, it involves the whole of the amalgam surface that is exposed, and the glass becomes worthless as a reflector. The continuity of its reflecting surface is destroyed, and it ceases to reflect the outlines of objects with precision. To avoid this trouble, care should be taken in hanging; if a glass is placed where the direct rays of the sun can strike it, it should be covered during that part of the day in which it is so exposed. It is better, of course, to hang it where it will not be exposed; but this is not always convenient, especially with large and expensive glasses, for which in modern houses there is usually provided a space for their reception.

Where granulation has already commenced, its further progress may often be checked, and the glass preserved, by simply changing its position. As above remarked, looking-glasses will be spoiled as well by the action of heat, as by that of direct sunlight. It is, therefore, important to avoid hanging a mirror near a stove or fire-place, where strong radiant heat will reach it. If this precaution is neglected, granulation is likely to occur, even in a comparatively dark room, from the action of heat instead of light. Another thing to be avoided, is having a lamp or gas jet burning too close to the glass, for though the heat may not be sufficient to crack the glass, it will often bring about the same injurious granulation. By observing the precautions above given, many of our readers may avoid future difficulty. A looking-glass can be re-silvered for about one-sixth or one-fifth of its original cost.

EMPLOYMENT OF MULES IN COAL MINES.—Upwards of 1,700 mules employed by the Philadelphia and Reading Railroad Coal and Iron Co's, in connection with mining operations toil underground daily. At many of the mines the mules do not see the light of day for a year at a time, and very often a mule spends ten years of his life underground. The effect of daylight upon mules that have been so long in darkness is blinding. In many instances this blindness is permanent, the shock of sudden light being too great for the eyes; but it is the general rule that the mule staggers around in blindness for a few days, always, however, finding his way to the feeding bin, and taking true aim with his heels. At the end of the week, eyesight returns; he brays with all the vigor of lung for which his kind is celebrated, elevating his tail as an accompaniment. There are, in round numbers, 2,300 mules employed in all capacities by these companies. Many of them are taken up and down on the cage at the mines daily. In an economic point of view, they are said to be 33% cheaper than horses, but that this is offset by the risk run in employing them.

THE GLUCOSE BUSINESS.—It is stated by those connected with the trade, that the glucose business is in a bad way; that most of the factories throughout the country are closed, and that glucose is selling at a lower price than when corn was but 30 cents a bushel. The enormous profits realized by those who first went into its manufacture created a boom which led to the building of factories all over the country, till there has been an over-production. Meanwhile, the novelty has worn off, and the public has learned that it is a spurious, bastard product, having a low intrinsic value, and its use and consumption have greatly fallen off in favor of straight sugar goods. The charges that it is objectionable on sanitary grounds, and injurious to health, have never been proved, and it is doubtful if they can be sustained. Its growing unpopularity arises mainly from the fact of its low sweetening properties, only about two-fifths that of sugar syrups, together with more or less of prejudice, on the ground that it is unwholesome. —*Chicago Grocer.*

CORK SHAVINGS FOR VINEGAR.—The wood shavings commonly employed in vinegar factories preserve their activity for a certain length of time, and then become useless. Bersch explains this on the supposition that the shavings, becoming saturated with liquid, get heavier, and press down on those beneath so hard as to prevent the air from circulating through them. He, therefore, recommends the substitution of the waste cork from which stoppers, etc., have been cut, for the wood chips. The elasticity of the cork is increased by moisture, so that they cannot pack together, even in the tallest tanks. Small organisms exist in the pores of the cork, and among these, many vinegar bacteria, so that the cork is very active in making vinegar.

ELECTRICAL GLASS CUTTING.—At present, large glass cylindrical vessels for scientific and commercial purposes are cut during manufacture by surrounding them with a thin filament drawn out from the molten glass, and then cooling them suddenly by contact with a cold substance. A more sure and perfect method has been devised by Herr Fabolt, of Dresden, who surrounds the glass with a copper wire, connected by binding screws with the two poles of a galvanic battery, and made red-hot by forming contact. The rough edges are then rounded off by turning the object round in a blowpipe flame; and, to prevent any unequal contraction of the parts subjected to this action, a slight annealing is effected in the furnace—*Iron.*

SPEED OF CANNON BALLS.—The highest velocity that has been imparted to shot is 1,626 ft. per second. This is equal to a mile in 3.2 seconds. The velocity of the earth at the equator, due to rotation on its axis, is 1,000 miles per hour, or a mile in 3.6 seconds. Therefore, if a cannon ball were fired due west, and could maintain its initial velocity, it would beat the sun in its apparent journey round the earth.

THE BEST QUALITY OF CHARCOAL is made from oak, maple, beech and chestnut. Wood will furnish, when properly charred, about 20 per cent of coal. A bushel of coal from pine weighs 29 pounds; a bushel of coal from hardwood weighs 30 pounds; 100 parts of oak make nearly 23 of charcoal; red pine, 22.10; white pine, 23.—*Exc.*

AN ELECTRIC RAILWAY, for the purpose of carrying passengers around the inside of the gallery of the building, will be one of the features of the Exposition of Railway Appliances to be held in Chicago, May next. The length of this railway will be about one-third of a mile.

MEN TO A MILE.—The total number of employees on the 22,184 miles of railway belonging to roads terminating in Chicago, as reported to the State railroad commissioners, is 111,023. This is almost exactly five men to a mile.

GOOD HEALTH.

The Care of Infants.

EDITORS PRESS:—Having read in the *Rural Press* an inquiry from a lady in Napa, for a remedy for costiveness in infants, and after answering the mother, C. D., by letter, I fear she may not look for an answer through the mail as she did not give her full name, so I take my pen to tell you what I know about children. Give them plenty of warm flannel, good care and good air, a bath every morning in a warm room, in water about blood-warm, have a bath-sheet to dry them in—never a towel, as it chills them. Dry and rub with a warm hand thoroughly, dust with ground starch or French-powder, dress in loose warm flannel, and a slip without starch around neck or sleeves. Let them sleep, sleep, sleep. Never trot or jump the baby.

Feed as regularly as one can, with meals not too near together (though I never could feed by rule) I found all the grain, excellent cooked without sifting, but cook well, and the milk of one cow, best a young new milch cow, that grew with baby.

I found an infant syringe indispensable to have healthy, regular children. I use water about the temperature of the bath, with a little castile soap in the water given with the infant syringe every morning, before or after bath, all that baby needed, and some of my children have never had medicine for costiveness, and never any of them had colic, as is usual with babies, although I never ate cabbage, or pickles, or vinegar, or stimulants of any kind while nursing. They would sleep all night and play all day, when awake, with one exception. My baby boy, born the 27th of December, in very cold weather, under care of the nurse, in drying and powdering, although very careful, the skin was broken, and it was quite bad before I felt it was serious at all. It continued to get worse, and I thought it must be kept scrupulously clean; a mistake however, as I did not give the tender new skin time to form and heal. I sent for Dr. Robinson, of Colusa. He is on the State Board of Health, and one of the best doctors in the interior. He gave me zinc salve to put on and leave alone. It acted like magic, and since then one of my neighbor's baby boys had the same trouble very badly. I sent some of the salve to the distracted mother (for the child screams continually with the soreness), and it cured her child, and now they are never without the salve in the house. I am sure Dr. Robinson will not object to my writing this after seeing how my poor baby was relieved.—*MRS. LITA M. PETERSON, Maxwell, Cal.*

BLOOD DIET.—A French savant, M. Regnard, has been lately trying the effect of a "blood diet" on lambs. Three lambs, which for some unexplained cause had been abandoned by their mothers, were fed on "powdered blood" with the most gratifying results. The lambs increased in size in the most marvelous fashion, and attained unusual proportions for their age. The coats of wool also became double in thickness. Encouraged by his success with the lambs M. Regnard is now feeding some calves on blood.

Treatment of Heart Disease.

There seems to be almost everywhere, a growing complaint of heart affections, and the *Medical and Surgical Reporter*, of New York, had an article recently on this subject, in which rest is recommended as the best remedy for some kinds of heart troubles.

By this, says the editor, we mean not positive, but comparative rest; neither do we refer to inflammatory affections of the heart, wherein, from the very gravity of the disease, confinement to bed and consequent rest become necessarily assured. We are thinking of those cases of heart exhaustion, so to speak, of individuals whose general health and tonicity is much run down, from overwork or abuse, and in whom the heart shares in this general vitiation. Possibly the organ is not in itself diseased; its organic integrity may be perfect, but its muscular walls may be flabby and weak, ready to yield, or, more properly, unable to resist any great strain. If, when in this condition, the man resorts to any violent muscular exercise, or subjects himself to the influence of violent physical emotions, this weak heart may become mechanically distended in its efforts to perform the extra labor demanded of it. Or, it may be, that dilatation has already taken place to some extent; then does it become important to allow the organ time for the development of the beneficent hypertrophy that will do so much to preserve its integrity.

By rest we mean to advise your patients who are threatened with or already have dilatation of the heart to do everything slowly, to perform every act of life deliberately, and to avoid, as far as possible, all occasions calculated to excite the passions or emotions. We must ever remember what a delicate machine the heart is, and how easily it can become deranged, and realizing this, must consider how much more care this organ requires when it is already diseased. We must, under such circumstances, walk slowly, think slowly, eat slowly—in a word, do everything slowly. It is not well, and we do not recommend the carrying of this advice to the verge of laziness; but what we do mean is that while it is well for all (either sound or diseased) to avoid hurry, it is 10 times more important, aye, absolutely imperative, for the man with a weak or diseased heart.

MALARIA IN NEW ENGLAND—SUGGESTIVE

FACTS.—A short time ago the key to the mysterious extension of malarial diseases in New England was supposed to have been found in the damming of the streams for manufacturing purposes. Now the *Boston Advertiser* says that intelligent people living in the districts invaded, say that the appearance of malaria in New England dates from the introduction of the cultivation of tobacco on a large scale upon the intervals of the Connecticut, and that its spread has kept even pace with the extended growing of this crop. The most plausible theory of the introduction and propagation of the aerial poison is this: The tobacco crop is a proverbially exhaustive one. To keep up the productiveness of the soil fertilizers are freely used. The manure is brought from New York City, mostly in scows, which are unloaded on the banks of the river where the cargo is to be used. All the autumn and winter these heaps of putrid matter are fermenting and breeding disease. The air that comes in contact with these piles of filth is contaminated and rendered unfit for human lungs to inhale, as it is offensive to the senses.

THE DECAY OF TEETH.—From a recent examination by Dr. Franzius, of the teeth of 650 soldiers in Russia, it appeared that 258, or nearly 40% had dental caries. He finds that, of all the teeth, the third molar is most often affected, such cases making up one-half of all the cases. The teeth are affected in a certain successive order; first the lower third molar is attacked, then the upper, then the lower fourth molar, and so on. The incisors and the canine teeth of the lower jaw stand last in the line. The durability of the upper teeth stands to that of the lower as three to two. The teeth in persons of fair complexion and hair are less durable than those of dark complexion and hair (40 to 37%). Stature has a manifest influence on the durability of the teeth, which increases with decrease of height, and *vice versa*. (Dr. Franzius seeks an explanation of this curious fact in a less perfect outer circulation in tall men than in short men.) The right teeth show a greater vitality than the left. The conditions of the soldier's life do not show any harmful influence on the state of the teeth.

GENERAL PARALYSIS.—Dr. Philip Teuner, in the *Cincinnati Lancet and Clinic*, defines the disease as an affection of the anterior portion of the cerebrum, of that part which the study of comparative anatomy and anthropology indicates to be the seat of intelligence, and which modern experimental investigations indicate to contain the motor centers. The pathological anatomy consists of changes in the membranes of the brain, usually most marked in the anterior portions, as well as changes in the cortex and subcortical regions, affecting chiefly the anterior cerebral convolutions. Its earlier symptoms consist chiefly of morbid manifestations of intelligence, such as want of judgment, loss of memory, boastfulness, etc., and of failure of the motor functions occurring simultaneously and progressing correlatively with the mental disturbances.

TABLE OF CONTENTS.

EDITORIALS.—Placing Frue Concentrators; Working Blue and White Cement, 145. Passing Events; Duty of a Miner's Inch of Water; The Albion Mine Difficulty; Processes for Silver Ores; Tunnel Locations, 152. Mine Timbering—No. 4, 153. Patents and Inventions; Notices of Recent Patents, 156.

ILLUSTRATIONS.—Arrangement of Shafts and Pulleys for Quarter-Twist Belt; Proper Position for Frue Concentrator with Relation to Battery in Gold Mill, 145. Scale Insects Infesting the Rose, the Juniper and the Euonymus, 150. Timbers for Mines, 153.

MECHANICAL PROGRESS.—“Steel-Iron;” Aid of Machinery to Labor; Forging a Rudder; A Smokeless Locomotive; Paper or Cast-Iron for Car Wheels; The Manufacture of Bessemer Steel, 147.

SCIENTIFIC PROGRESS.—Sweeping the Skies; Man and Animals; Absorption of Hydrogen; How a Man Walks; A New Danger; A Thermostat Current Meter; Jupiter's Spot; Studying Nature, 147.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends and Bullion Shipments, 148.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Colorado, Idaho, New Mexico, Oregon and Utah, 149-9.

THE ENGINEER.—American Steamboats Sweep the World; A Remarkable Record for Safety; Railroad Business; American Railroad System for Japan, 151.

USEFUL INFORMATION.—Spotting of Looking Glasses; Employment of Mules in Coal Mines; The Glucose Business; Cork Shavings for Vinegar; Electrical Glass Cutting; Speed of Cannon Balls; Men to a Mile, 151.

GOOD HEALTH.—The Care of Infants; Blood Diet; Treatment of Heart Disease; Malaria in New England—Suggestive Facts; The Decay of Teeth; General Paralysis, 151.

MISCELLANEOUS.—Wyoming Mines; The Fauna of Arizona; An English Zinc Mine; A Government Asked for Alaska; California Production and Commerce, 149. How to Forestall Frost; Diapirine; Genesis of Metalliferous Veins, 150.

NEWS IN BRIEF.—On page 149 and other pages.

BUSINESS ANNOUNCEMENTS.

Dividend Notice—Bulwer Con. Mining Co., S. F. Iron Shale Riffles—A. B. Paul, San Francisco.

Passing Events.

The lack of rain is causing some uneasiness. There is very little snow in the mountains, and the miners now think they will have a very short water season. It is said there is less snow on the high ranges than was ever known at this season in the history of the State.

It is worthy of note that, in the old Tahle Mountain mines, some very good results have lately been developed. In the old New York claim they have been taking out some gravel worth \$10 a pan, and several of the other claims are doing well. Most of the mines are old ones, worked years ago, and left idle for a long time.

The warm weather of late has been an incentive to prospectors to get ready for their work, as spring will soon be here. It is probable that this season there will be more prospectors on foot than ever before. Idaho, Montana and New Mexico will no doubt be the favorite fields, and there will be some little emigration to Alaska. The mining field on this coast is a very broad one, however, and there is plenty of room for earnest workers.

BRITISH COLUMBIA.—We intend publishing, next week, a double edition of the MINING AND SCIENTIFIC PRESS devoted specially to the interests of British Columbia. We have prepared a fine large map, showing the main geographical features of the region. It also shows the mining regions and the general geology. With this will be a descriptive article by a gentleman who is familiar with British Columbia, and more particularly with its mining territory. The PRESS, in addition, will contain its usual varied contents and numerous illustrations.

Duty of a Miner's Inch of Water.

What percentage of the material removed from hydraulic mines comes down into the valley it is impossible for any one to state with exactness, there not being sufficient data at hand to enable any engineer, no matter how competent, to make an exact estimate. Such data can only be obtained by elaborate surveys.

The best and most accurate method for determining the quantity of solid material discharged at the dump of a hydraulic mine, is to ascertain the “duty” of a miner's inch of water on that particular mine; or in other words, the number of cubic yards that is removed by a miner's inch of water when used consecutively for 24 hours. Testimony elicited in the pending case of Woodruff against the North Bloomfield Mining Co., shows that after a series of very careful experiments and observations made by the most competent persons, at a time long before litigation was commenced, and when there was certainly no object in producing incorrect or exaggerated results, almost certainty has been and can be arrived at by that method.

A “miner's 24-hour inch” of water is 2,230 cubic feet. A careful measurement of the cubic contents of a portion of the mine is made for the purposes of this demonstration, and that portion is washed away; the number of inches of water used and the length of time occupied in the removal of the bank being carefully noted, a simple calculation gives the duty of a miner's 24-hour inch on that bank.

For the purpose of ascertaining the quantity of solid material which is carried by the water to the end of the flume (or dump), we multiply the number of miner's inches by 24 hours, used in the mine, by the duty of each inch, and the product represents the amount of material used. Thus, for instance, at the Bloomfield mine careful measurements, numbering through a series of years, show that now the duty of an inch at that mine is three and one half cubic yards. A stream of 2,800 inches is used per day; here there are 9,800 cubic yards washed into Humbug canyon, each day the mine is at work at its fullest capacity.

To determine the percentage of solid material carried by the water, we multiply three and one half yards by 27, giving 94½ cubic feet; dividing this by 2,230, the number of cubic feet represented by a miner's inch, there results four and one third per cent. of material carried by the water, including not only that held in suspension, but also that rolling along the bottom of the flume.

This shows that the statement of some persons that eight per cent. of solid material passes in suspension from these mines is incorrect. To carry eight per cent. of sediment, both in suspension and rolling along the bottom of the flume, according to the rule stated, the correctness of which cannot be successfully disputed, it would require from the mines referred to nearly seven cubic yards per 24-hours' inch. Observations show that at the Excelsior mine the duty of a miner's 24-hours' inch does not exceed two cubic yards, which gives about two and one quarter per cent. carried by the water to the dump. At the Milton mine the duty is two and four tenths cubic yards, or about three per cent. carried to the dump. At the North Bloomfield mine the duty is three and one half cubic yards, or about four and one third per cent. discharged from the flume.

The Albion Mine Difficulty.

Our Eureka correspondent, Mr. Joseph, sends us the following note in the matter of the Albion mine, under date of February 26th: “No such failure in the management of a promising, and no doubt valuable mine, has ever been recorded in Eureka district as that of the Albion. During the long course of litigation that followed the first discovery of an ore body in the mine, the sympathies of the people of Eureka were with the Albion Co., for the reason that they desired to have three large companies operating in the district in place of only two. To-day the same people are almost unanimous in the wish that the Richmond Co. had won every suit and held every inch of ground for which they fought. During the past week attachments have been levied amounting to \$75,000, and liens have been filed for about \$15,000. It is estimated that \$20,000 additional will cover the amount of the company's indebtedness in Eureka. I learn that \$110,000 will cover the amount of the San Francisco indebtedness.

The total indebtedness of the company is variously estimated from \$220,000 to \$320,000. No one however knows positively but inside parties. While several of the miners have filed liens, there are some who will not, they expressing belief that the mine will come out all right. There is a difference of opinion as to the mine, some of the miners freely stating that it looks better to-day than it ever did, and others to the contrary. Mr. Williams, the foreman, says that ore has been struck on the main (335 foot) level, in the Uncle Sam crosscut. This result of this reckless management is a severe blow to our camp, and what the outcome will be, it is impossible to foresee.

Processes for Silver Ores.

The great variety of processes still employed for the extraction of silver in different parts of the world, and each one possessing advantages over the others for the treatment of the ores of particular localities, are rendered necessary by the great diversity existing in the associates of the metal, the very large amount of materials that it is necessary to operate upon, owing to the argentiferous minerals often occurring minutely disseminated through large proportions of an earthy gangue, more or less intimately mixed with ores or compounds of other metals, as galena, copper ores, etc. The methods employed for the separation of metallic silver from its ores, or metallurgical products, in which it exists in notable quantity, may, however, be classed under three heads. The different methods of amalgamation employed, based upon the solubility of metallic silver in mercury, and the subsequent ready expulsion of the latter on the application of heat to the amalgam include:

1. The Mexican methods of amalgamation in heaps.
2. The European system of amalgamation in casks, known also as the “barrel process.”
3. The methods of amalgamation in kettles or pans.

There are various wet methods for the extraction of silver from its sulphides by first converting them into chloride or sulphate, which is then dissolved out by water, solution of common salt, or other suitable solvent, and the silver subsequently deposited by precipitation from the solution so obtained, these methods including—

1. “Angustin's” method, by which the ore, or cuprous regulus, is converted into argentic chloride, which is then extracted by a solution of sodic chloride, and the silver afterwards precipitated by metallic copper.
2. The method of “Ziervogel” for the conversion of argentic sulphide into sulphate, which is subsequently dissolved out by hot water, and the silver precipitated as cement silver, as in the Angustin process.
3. The method of “Von Paterna,” by which the argentic sulphide is converted into chloride, which is then dissolved out by a solution of sodic hyposulphite, from which the silver is reprecipitated as argentic sulphide freed from other metals, the sulphide being then reduced by the application of heat.

Then there are the methods in which the silver is concentrated in a quantity of lead, from which it is subsequently separated by the process of cupellation. The silver is argentiferous copper matte, or other regulus, which was formerly separated by amalgamation methods, etc., is frequently separated by these methods, and very rich silver ores are also treated by these methods; while, in fact, all silver ores may be treated by fusion with galena or other lead-yielding product, with the separation perhaps of a larger portion of silver than is effected by the amalgamation processes; but owing to the scarcity of fuel in certain localities, and the expense, this method cannot be applied, and the methods of amalgamation are there accordingly more convenient and economical.

ALTHOUGH they are unable at present to get their ores reduced, on account of the freezing up of the water mills, the miners down about Silver City are still hard at work in their mines. It is said that work is being done on not less than 30 little mines down in that neighborhood, from all of which more or less paying ore is being taken out.

The Lake Superior (Mich.) iron mines produced 2,943,300 tons of ore in 1882, valued at \$24,237,200. The iron product of Michigan is of more value than the silver product of any State in the Union.

Tunnel Locations.

Miners generally do not seem to understand as clearly as they should the provisions of the laws regarding tunnel location, either as to the rights of the locators themselves or those discovering or owning claims near the line. We will endeavor in this article to point out such facts as prospectors and miners should remember in this connection.

It has always been the policy of the Government—as shown by the statutes providing for the disposal of the public lands containing minerals—to prevent an individual or company from acquiring title to large tracts of mineral land. Because, therefore, men start a tunnel into a hill, it does not give them the right to the hill or to a tract 3,000 feet long and 1,500 feet wide, as many persons erroneously suppose to be the case. This would be a hundred acres or so, and there is no authority for locations of this size, either in any local law or Congressional enactments.

Section 2,323 of the Revised Statutes provides that where a tunnel is run for the development of a vein or lode, or for the discovery of mines, the owners of such tunnel shall have the right of possession of all veins or lodes within 3,000 feet from the face of such tunnel on the line thereof not previously known to exist, discovered in such tunnel, to the same extent as if discovered from the surface, and locations on the line of this tunnel, of veins or lodes not appearing on the surface, made by other parties after the commencement of the tunnel, and while the same is being prosecuted with reasonable diligence, are invalid; but failure to prosecute the work on the tunnel for six months is considered an abandonment of the right to all undiscovered veins or lodes on the line of the tunnel. This is not an abandonment of ledges found.

The effect of this is simply to give the proprietors of a mining tunnel, run in good faith, the possessory right to 1,500 feet of any blind lode cut, discovered or intersected by such tunnel, which were not previously known to exist, within 3,000 feet from the point of commencement of the tunnel, and to prohibit other parties, after the commencement of the tunnel, from prospecting for and making locations of lodes on the line thereof, and within the distance of 3,000 feet, unless the lodes appear on the surface as were previously known to exist.

The term “face” is construed to mean the first working face formed on the tunnel, and to signify the point at which the tunnel actually enters cover; it being from this point that the 3,000 feet are to be counted, upon which outside prospecting is prohibited.

To avail themselves of the benefits of this provision of law, the proprietors of the tunnel have to give notice of the location, and carefully mark lines and boundaries, the actual or proposed course or direction of the tunnel, height and width thereof, etc. The Land Office takes particular care that no improper advantage is taken of this provision of law, by people who make locations to attempt to monopolize the lands lying in front of their tunnels, to the detriment of the mining interests and exclusion of bona fide prospectors.

We have italicized the words in the law speaking of the line of the tunnel; because the line of the tunnel is held to be the width thereof and no more, and upon this line only is prospecting for blind lodes prohibited while the tunnel is in progress. The width of the location is restricted to the actual width of the tunnel now. For instance, if a tunnel is six feet wide, the location covers 3,000 feet long and six feet wide. On either side of this any one may prospect and take up such claims as he may find.

Stakes or monuments are to be placed along the line of the tunnel to mark its course and position. The tunnel is a means of discovery. When a lode is discovered, the tunnel proprietor must proceed in locating his surface ground, staking it off, posting notice, recording, etc., as if the mine was discovered from the surface.

Upon a line represented by the width of the tunnel, prospecting for blind lodes is prohibited while the working of the tunnel is in progress; and the right is granted to the tunnel owner to 1,500 feet of each blind lode not previously known to exist, which may be discovered in the tunnel; but other parties are no way debarred

from prospecting for blind lodes or running tunnels so long as they keep without the line of the tunnel; the said line being required by regulation to be marked on the surface by stakes or monuments. When a lode is struck by running a tunnel, the owners have the option of recording their claim of 1,500 feet all on one side of the point of discovery, or partly on one side and partly on the other; but in no case can they so record a claim as to absorb the actual or constructive claim or possession of other parties on a lode which has been discovered and claimed outside the line of the tunnel, before the discovery thereof in the tunnel.

Locators of tunnel rights are expected to use reasonable diligence in working and advancing their tunnel. There is no specified amount to be expended to retain the ownership of tunnels; but the law provides that if no work is done in six months it is a virtual abandonment of the right to all undiscovered veins on the line of the tunnel.

It has been decided that no patents can issue for a vein or lode without surface ground. Therefore it is held that the survey of a vein or lode discovered in a tunnel, can not properly be made until the apex thereof has been ascertained by sinking a shaft or by following it upon its dip from the point of discovery.

There is no provision of law for patenting tunnel locations. Such lodes, however, as are discovered in running the tunnel may be patented in the usual way.

The Act of February 11, 1875, credits to a lode claim the expenditures made in running a tunnel for the purpose of developing the lode owned by the proprietors of the tunnel. No surface work will then have to be done to hold the claim.

The right of possession of veins or lodes granted by Act of Congress to tunnel owners, is dependent, among other things, upon discovery of the vein or lode in the tunnel. The effect of the Act is to give a party running a tunnel for any purpose, whether for prospecting or development, the right to pre-empt and locate any and all lodes not previously known to exist, discovered in such tunnel, to the same extent as if discovered from the surface.

If, by local custom, the owner of one mining claim has a right to construct a tunnel through an adjoining claim, in order to enable him to work his own claim, a Court of Equity may enjoin any interference with that right.

An expenditure of more than \$1,500 by the owners of an adjoining claim on the portion of a tunnel running through the premises embraced in an application for patent, in case the applicants were to have an interest in such tunnel, is considered an expenditure, under the mining law, upon the claim applied for.

Where a lode had been discovered and located on the surface, and it remained in doubt whether it was the same lode which had been entered by a tunnel below, and the said tunnel was prosecuted for blind lodes, as well as for the lode discovered on the surface, a Nevada Court has held that not only could the *habendum* of a deed which was uncertain as to its conveyance of the ledge be used to explain or qualify the description of the granting clause, but that parol evidence was admissible to show the circumstances under which the deed was made, to reach the intent of the parties as to the ledge.

It will be seen that where there has been a total abandonment of, or a failure to prosecute work on a tunnel for six months, the party or parties claiming the tunnel forfeit the right to the undiscovered veins on the line. Should either of the parties claiming the tunnel refuse or fail to contribute his proportion of the expenditures required by Section 2324 upon a lode owned by them, or in running a tunnel for the purpose of developing a particular lode or lodes owned by them, the co-owners who have made the required expenditure may proceed against the delinquents in the ordinary manner prescribed for lode claims. This is an important point for miners to remember.

As we have before stated, a tunnel site under the law cannot exceed in length 3,000 feet, and the width is the actual width of the tunnel itself. The Commissioner of the Land Office has decided that a tunnel owner would have the right to the timber growing upon this tract, so long as he complies with the law in running the tunnel.

It was decided in a Nevada court, in the case of Bullion M. Co. vs. the Croesus M. Co., that "when a suit is brought for a blind ledge,

bounded by walls found at a depth of 200 feet below the surface, the ledge only, and no part of the surface can be recovered.

We append the form of a location certificate for a tunnel claim:

Know all men by these presents, that the undersigned, citizens of the United States, have this _____ day of _____ 188____, claimed by right of location, a tunnel claim, for the purpose of discovering and working veins, lodes or deposits on the line thereof [cutting the _____ lode, and working the _____ lode.] Said tunnel claim is situated in the _____ mining district, county of _____, State of _____, and the location and bounds of said tunnel are staked on the surface at the place of commencement and termination thereof. Said claim is more particularly described as follows: [Describe the commencement and termination by reference to natural objects and permanent monuments, and the line by courses and distances.] Dated _____, 188____, _____, Locator.

These facts, which we have taken some little trouble to compile from the U. S. Revised Statutes, decisions of the courts, decisions of Secretary of the Interior and rulings of the U.

Mine Timbering—No. 4.

Timbering of Shafts.
